### (54) Information processing apparatus and method for use in system with remote printer

(57) A host computer acquires information about an amount of remaining ink of a printer. In response to the acquired information about the amount of remaining ink, the host computer displays a message on a display

screen so that a user can select whether an ink cartridge is to be replaced with a new one or the process is to return to a previous routine without replacing the ink cartridge.

FIG. 1

EP 0 707 969 A2

**Description****BACKGROUND OF THE INVENTION**5 **FIELD OF THE INVENTION**

The present invention relates to an information processing system such as a host computer for controlling a printing apparatus such as an ink-jet printer that performs a printing operation by firing droplets of ink at paper through a nozzle of a print head wherein the ink is supplied from an ink reservoir to the print head, and also relates to an information processing method for handling such a system.

**DESCRIPTION OF THE RELATED ART**

An ink-jet printer has the capability of detecting the amount of remaining ink, which prevents a printing error which would otherwise occur due to lack of ink. According to this capability, the amount of ink remaining in an ink reservoir is detected and the result is displayed. If the detected amount becomes less than a lower limit, a warning is given or a printing operation is stopped.

There are various known techniques for detecting the amount of ink remaining in an ink reservoir, and some of them are in practical use.

20 One of the techniques is to dispose a proper sensor in an ink reservoir so as to directly detect the amount of remaining ink. For example, two electrodes are disposed in an ink reservoir in such a manner that the electrodes are in contact with ink so as to detect the resistance between the two electrodes that changes depending on the amount of remaining ink. In another technique similar to the above first technique, a light beam is used to illuminate ink in an ink reservoir. If there is ink in the ink reservoir, the light beam is absorbed by the ink and cannot reach a photodetector. On the other hand, 25 if no ink is in the ink reservoir, the light beam can travel through the ink reservoir without being absorbed, and can reach the photo detector. Thus, it is possible to detect whether there is ink in the ink reservoir. Hereinafter, the above-described methods will be referred to as a sensor method.

In a second category of methods, the number of operations of emitting ink droplets via a print head is counted, and the result is compared with the previously estimated maximum possible number of printing dots or the maximum number 30 of ink droplets that can be supplied from one ink reservoir thereby indirectly estimating the consumption of ink. Hereafter, this technique is referred to as a "dot counting method."

The printing apparatus having the capability described above is controlled by a host computer. However, the host computer cannot know the status regarding the amount of remaining ink of the printing apparatus, and thus cannot tell a user the status in a visual or other fashions.

35 To obtain a good result in printing, the ink-jet printer has to know the status of the printer with respect to the items including those described below.

First, the printer has to detect the distance between paper or printing medium and the ink emission plane of a print head so that printing is performed correctly at desired positions.

In conventional printers, as shown in Figures 38 to 40, there is provided a lever 301 for adjusting the paper position. 40 By using this lever, the paper position is switched between a standard paper position and a thick paper position so as to optimize the paper position for both standard paper and thick paper such as a post card.

In the above-described conventional printing system, if the system has a fatal error associated with for example the paper position adjustment, the error is indicated only on the printer via audio or optical means. Therefore, the user has to come to the printer to know what error the printer has, and then has to handle the error, which is very inconvenient 45 for the user.

Furthermore, in the conventional printing system the user cannot know the type of printing medium via a display of the host computer.

**SUMMARY OF THE INVENTION**

50 It is a general object of the present invention to solve the above problems. More specifically, it is an object of the present invention to provide an information processing system and method for acquiring remaining-amount information representing the amount of ink remaining in an ink cartridge of a printer and displaying a message on display means in response to the acquired remaining-amount information so that a user can select either replacing of the ink cartridge in the printer or returning to a process performed by the information processing system.

It is another object of the present invention to provide an information processing system and method for: analyzing the color so as to determine the color to be used by a printing apparatus; acquiring remaining-amount information from a printing apparatus, the remaining-amount information representing the amount of ink of the determined color remaining in an ink cartridge; and displaying a message on display means in response to the acquired remaining-amount infor-

mation so that a user can select either replacing of the ink cartridge containing the ink having the color to be used or returning to a process performed by the information processing system.

It is still another object of the present invention to provide an information processing system and method for: judging whether the printing mode of a printing apparatus is a monochrome mode or a color mode; acquiring remaining-amount information from the printing apparatus in response to the judgement result, the remaining-amount information representing the amount of ink remaining in a color ink cartridge to be used; and displaying a message on display means in response to the acquired remaining-amount information so that a user can select either replacing of the ink cartridge containing ink of the color to be used or returning to a process performed by the information processing system.

It is a further object of the present to provide an information processing system and method for: acquiring remaining-amount information representing the amount of ink remaining in an ink cartridge disposed in a printing apparatus; and displaying a message on display means in response to the acquired remaining-amount information so that a user can select either replacing of the ink cartridge in the printing apparatus or designation of an alternative color different from the color of the ink in the above-described ink cartridge.

It is another object of the present invention to provide an information processing system and method for: acquiring remaining-amount information representing the amount of ink remaining in an ink cartridge disposed in a printing apparatus; and displaying a message on display means in response to the acquired remaining-amount information so that a user can select either designation of an alternative color different from the color of the ink in the above-described ink cartridge or returning to a process performed by the information processing system.

It is another object of the present invention to provide an information processing system and method for: comparing the number of dots contained in dot image information with the number of dots that can be printed by a printing apparatus; and controlling the generation of the dot image information depending on the result of the above comparison.

The above objects are achieved by the present invention having various aspects as described below. According to an aspect of the present invention, there is provided an information processing system for controlling a printing apparatus, including: acquisition means for acquiring remaining-amount information representing the amount of ink remaining in an ink cartridge disposed in the printing apparatus; and display control means for controlling display of a message on display means in response to the acquired remaining-amount information, the message advising a user to select either replacing of the ink cartridge in the printing apparatus or returning to a process performed by the information processing system.

According to another aspect of the present invention, there is provided an information processing system for controlling a printing apparatus, including: analysis means for analyzing a color to be used by the printing apparatus; acquisition means for acquiring remaining-amount information from the printing apparatus, said remaining-amount information representing the amount of ink remaining in an ink cartridge, the ink having the color analyzed by the above analysis means; and display control means for controlling display of a message on display means in response to the acquired remaining-amount information, the message advising a user to select either replacing of the ink cartridge containing ink having the color to be used by the printing apparatus or returning to a process performed by the information processing system.

According to still another aspect of the present invention, there is provided an information processing system for controlling a printing apparatus, including: judgement means for judging whether a printing mode of the printing apparatus is a monochrome mode or a color mode; acquisition means for acquiring remaining-amount information from the printing apparatus in response to a judgement result by the above judgement means, the remaining-amount information representing the amount of ink of a color to be used remaining in an ink cartridge; and display control means for controlling display of a message on display means in response to the acquired remaining-amount information, the message advising a user to select either replacing of the ink cartridge containing ink of the color to be used by the printing apparatus or returning to a process performed by the information processing system.

According to another aspect of the present invention, there is provided an information processing system for controlling a printing apparatus, including: acquisition means for acquiring remaining-amount information representing the amount of ink remaining in an ink cartridge disposed in the printing apparatus; and display control means for controlling display of a message on display means in response to the acquired remaining-amount information, the message advising a user to select either replacing of the ink cartridge in the printing apparatus or designation of an alternative color different from a color of the ink in the ink cartridge.

According to another aspect of the present invention, there is provided an information processing system for controlling a printing apparatus, including: acquisition means for acquiring remaining-amount information representing the amount of ink remaining in an ink cartridge disposed in the printing apparatus; and display control means for controlling display of a message on display means in response to the acquired remaining-amount information, the message advising a user to select either designation of an alternative color different from a color of the ink in the ink cartridge or returning to a process performed by the information processing system.

According to still another aspect of the present invention, there is provided an information processing system for outputting dot image information to a printing apparatus, including: comparison means for comparing a number of dots

contained in the dot image information with a number of dots that can be printed by the printing apparatus; and control means for controlling the generation of the dot image information depending on a result of the comparison means.

According to a further aspect of the present invention, there is provided an information processing method for use in an information processing system for controlling a printing apparatus, including the steps of: acquiring remaining-amount information representing the amount of ink remaining in an ink cartridge disposed in the printing apparatus; and controlling display of a message on display means in response to the acquired remaining-amount information, the message advising a user to select either replacing of the ink cartridge in the printing apparatus or returning to a process performed by the information processing system.

According to another aspect of the present invention, there is provided an information processing method for use in an information processing system for controlling a printing apparatus, including the steps of: analyzing a color to be used by the printing apparatus; acquiring remaining-amount information from the printing apparatus, the remaining-amount information representing the amount of ink remaining in an ink cartridge, the ink having the color analyzed in the above analyzing step; and controlling display of a message on display means in response to the acquired remaining-amount information, the message advising a user to select either replacing of the ink cartridge containing ink of the color to be used by the printing apparatus or returning to a process performed by the information processing system.

According to still another aspect of the present invention, there is provided an information processing method for use in an information processing system for controlling a printing apparatus, including the steps of: judging whether a printing mode of the printing apparatus is a monochrome mode or a color mode; acquiring remaining-amount information from the printing apparatus in response to a judgement result obtained in the judgement step, the remaining-amount information representing the amount of ink of a color to be used remaining in an ink cartridge; and controlling display of a message on display means in response to the acquired remaining-amount information, the message advising a user to select either replacing of the ink cartridge containing ink of the color to be used by the printing apparatus or returning to a process performed by the information processing system.

According to another aspect of the present invention, there is provided an information processing method for use in an information processing system for controlling a printing apparatus, including the steps of: acquiring remaining-amount information representing the amount of ink remaining in an ink cartridge disposed in the printing apparatus; and controlling display of a message on display means in response to the acquired remaining-amount information, the message advising a user to select either replacing of the ink cartridge in the printing apparatus or designation of an alternative color different from a color of the ink in the ink cartridge.

According to a further aspect of the present invention, there is provided an information processing method for use in an information processing system for controlling a printing apparatus, including the steps of: acquiring remaining-amount information representing the amount of ink remaining in an ink cartridge disposed in the printing apparatus; and controlling display of a message on display means in response to the acquired remaining-amount information, the message advising a user to select either designation of an alternative color different from a color of the ink in the ink cartridge or returning to a process performed by the information processing system.

According to another aspect of the present invention, there is provided an information processing method for use in an information processing system for outputting dot image information to a printing apparatus, including the steps of: comparing a number of dots contained in the dot image information with a number of dots that can be printed by the printing apparatus; and controlling the generation of the dot image information depending on a result in the comparing step.

According to the aspects described above, the host computer can acquire the status regarding the amount of remaining ink of the printing apparatus, and notify a user of the acquired status in a visual fashion so that the user can select the following operation via the display means.

Furthermore, another object of the present invention is to provide an information processing system and method for: acquiring information representing the distance between a print head of a printing apparatus and a printing medium; and displaying identification information about the printing medium in response to the acquired information, the identification information being set in the printing apparatus, thereby providing an improved user interface and ease of operation.

It is still another object of the present invention to provide an information processing system and method for: acquiring information representing an ink cartridge mounting status of a printing apparatus; and displaying a message on display means in response to the acquired information so that a user can select an alternative color different from a color of the ink in the above-described ink cartridge, thereby providing an improved user interface and ease of operation.

The above objects are also achieved by the present invention having various aspects as described below. According to an aspect of the present invention, there is provided an information processing system for controlling a printing apparatus, including: acquisition means for acquiring information representing the distance between a print head of the printing apparatus and a printing medium; and display control means for controlling display of identification information about the printing medium in response to the acquired information, the identification information being set in the printing apparatus.

According to another aspect of the present invention, there is provided an information processing system for controlling a printing apparatus, including: acquisition means for acquiring information representing an ink cartridge mounting status of the printing apparatus; and display control means for controlling display of a message on display means in response to the acquired information, the message advising a user to select an alternative color different from a color of the ink in the ink cartridge.

According to a further aspect of the present invention, there is provided an information processing method for use in an information processing system for controlling a printing apparatus, including the steps of: acquiring information representing the distance between a print head of the printing apparatus and a printing medium; and controlling display of identification information about the printing medium in response to the acquired information, the identification information being set in the printing apparatus.

According to another aspect of the present invention, there is provided an information processing method for use in an information processing system for controlling a printing apparatus, including the steps of: acquiring information representing an ink cartridge mounting status of the printing apparatus; and controlling display of a message on display means in response to the acquired information, the message advising a user to select an alternative color different from a color of the ink in the ink cartridge.

According to the above-described aspect of the invention, the information processing system can acquire information representing the distance between a print head of a printing apparatus and a printing medium and display identification information about the printing medium in response to the acquired information, the identification information being set in the printing apparatus, thereby providing an improved user interface and ease of operation.

Furthermore, the information processing system can acquire information representing the ink cartridge mounting status of a printing apparatus and display a message on display means in response to the acquired information so that a user can select an alternative color different from the color of the ink in the above-described ink cartridge, thereby providing an improved user interface and ease of operation.

## 25 BRIEF DESCRIPTION OF THE DRAWINGS

#### DESCRIPTION OF THE PREFERRED EMBODIMENTS

Referring to the accompanying drawings, a printing apparatus and a method of controlling it according to the present invention will be described in detail below.

#### EMBODIMENT 1

Figure 1 is a block diagram of a first embodiment of a printing system according to the present invention.

As shown in Figure 1, the printing system includes a printer 101 for printing image data, and a host computer 110 for receiving a command issued by a user and generating image data to be printed (printing information) wherein the printer 101 and the host computer 110 are connected to each other via an interface having the capability of bidirectional communication. The interface may be of any type such as that using a cable or a wireless interface using a radio wave or infrared light.

In this embodiment, an ink-jet printer is employed as the printer 101. The printer 101 includes: a controller (CPU) 102 responsible for controlling the entire printer; an operation panel 103 including a power on/off switch, an on-line switch for controlling the interface, and a lamp for indicating the status; a print head 104 for firing a droplet of ink at a printing material thereby printing an image thereon; a carriage motor 105 for moving a carriage, on which the print head is installed, in the vertical direction with respect to the print head; a paper feeding motor 106 for feeding, transferring, and pushing out a printing material; a memory 107 for temporarily storing data received from the host computer, and also storing image data (printing information) to be printed, wherein a unit of band size is employed as a storage unit; an ink sensor 108 for detecting the presence or absence of an ink cartridge and also detecting the amount of ink remaining in the ink cartridge; and a built-in font memory 109 for storing characters, pictorial characters, and the like which are expected to be used frequently. In this embodiment, the ink-jet printer is of the type having the capability of color printing, wherein the color printing is accomplished by a print head 104 having four heads for four colors including black, cyan, magenta, and yellow, these four heads being installed on a carriage. In this embodiment, the printer receives printing information (bit image information) band by band from the host computer 110, and then prints the received printing information on a printing medium band by band. In the case where the printer 101 is of the page printer type that performs a printing operation page by page, the host computer 110 may transmit the printing information to the printer 101 page by page. Furthermore, if the printer has the capability of converting the received data into a bit map form (generation of printing information), the host computer may transmit the printing information described in a printer language such as a PDL (Page Description Language) consisting of character and control codes to the printer band by band or page by page.

In the host computer 110, a CPU (not shown) develops bit map data (printing information) using an OS system 111 and application software 113 for producing documents, tables, and graphical images, in such a manner that the resultant bit map data meets the requirement of resolution needed by a printer driver 114. In the above process, character images consisting of vector information are developed into bit map data (printing information) using a font rasterizer 112. Furthermore, the CPU (not shown) generates printing information in the form suitable for a printing operation from the printing information developed into the form of bit map data using the printer driver 114. The CPU then adds printer control codes to it and transmits the resultant printing information to the printer. The printer driver 114 shows a user various information such as the status regarding the data processing as well as the printer status via a status window 115 at proper times.

The programs shown in the flowcharts of Figures 2-16 are stored in the printer driver 114 and executed by the CPU (not shown).

On the other hand, the program shown in the flowchart of Figure 42 is stored in for example a ROM (not shown) of the printer 101 and executed by a controller (CPU) (Figure 1). Referring to the flowcharts shown in Figures 2 and 3, the process of the present embodiment will be described below.

In step S101 shown in Figure 2, the program begins with receiving status information from the printer. In step S102, if a command is received which indicates that generation of printing information should be started, then in step S103 the program checks an ink cartridge flag. If the ink cartridge flag is 0, that is, all ink cartridges are mounted on the printer, then the program goes to step S104. In step S104, the program checks a no-ink flag. If the no-ink flag is 0, that is, there is ink in all the ink cartridges, then the program goes to step S105. In step S105, the program checks a remaining ink flag. If the remaining ink flag is 0, that is, the remaining amount of ink is enough, then the program goes to step S106. In step S106, printing information is generated by converting image information into a form suitable for printing band by band. In step S107, the generated printing information is then output to the printer band by band.

In this embodiment, the printing information is in the form of bit map data. However, if the printer 101 has the capability of converting the received data into bit map data, the printing information may be written in a printer language, such as a PDL, consisting of character and control codes.

If it is concluded in step S103 that the ink cartridge flag is 1, that is, some ink cartridge is not mounted on the printer, then the program goes to step S110 and the generation of printing information is temporarily stopped. Then in step S111, a message 1 is displayed. The message 1 is displayed in a status window on the display screen as shown in Figure 17. As shown in Figure 15, the status window contains a message indicating that a particular ink cartridge is not mounted on the printer and also indicating the color of that cartridge. The status window also contains "execute" and "stop" buttons. Either button may be selected via input means such as a mouse or a keyboard of the host computer, so that the selected operation will be executed. After mounting an ink cartridge according to the message shown in Figure 17, if the execution button is selected, it is determined in step S112 shown in Figure 2 that replacement of an ink cartridge has been performed, and the program then goes to step S301 shown in Figure 3. In the case where the stop button is selected in the status window of Figure 17, no ink cartridge is replaced in step S112 of Figure 2, and it is determined in step S113 that a forced aborting command has been issued, and thus the generation of printing information is canceled and the program returns to step S102 and waits until a command advising that generation of printing information should be started is issued again.

In the case where the program has branched to step S301, the message 4 is displayed. The message 4 is displayed in a status window on the display screen as shown in Figure 22. As shown in Figure 22, the status window contains a

message telling or advising that the printer will start cleaning the print head, and also contains "execute" and "stop" buttons. Either button may be selected via input means such as a mouse or a keyboard of the host computer, so that the selected operation will be executed. In the case where the stop button is selected, it is determined in step S302 of Figure 3 that a forced aborting command has been issued, and thus the generation of printing information is canceled and the program returns to step S102 of Figure 2 and waits until a command telling that generation of printing information should be started is issued again. Alternatively, in the case where it has been determined in the above step S302 of Figure 3 that a forced aborting command has been issued, the program may return to step S111 of Figure 2 so that the message shown in Figure 17 will be displayed again in the status window. If the "execute" button is selected in the status window of Figure 22, it is concluded in step S303 of Figure 3 that an "execute" command has been issued, and thus in step S304 a cleaning execution command is sent to the printer. On reception of the cleaning execution command, the printer sets the cleaning execution flag to 1 and starts the cleaning operation. When the cleaning operation is completed, the printer immediately resets the cleaning execution flag to 0. In step S305, if a cleaning completion signal indicating that the cleaning execution flag = 0 is received, the ink cartridge flag corresponding to the color of the cleaned ink cartridge is reset. Then in step S307, the generation of printing information is started again, and the program goes to step S104 of Figure 2. Alternatively, in the above step S306 of Figure 3, the flag may be reset by the printer itself instead of the host computer.

On the other hand, if it is concluded in step S104 of Figure 2 that the no-ink flag is 1 which indicates that there is no ink in an ink cartridge, then the program goes to step S114 at which the generation of printing information is temporarily stopped. Then in step S115, a message 2 is displayed. The message 2 is displayed in a status window on the display screen as shown in Figure 18. As shown in Figure 18, the status window contains a message telling that a particular ink cartridge has no ink in it and also telling the ink color of that cartridge. The status window also contains "execute" and "stop" buttons. Either button may be selected via input means such as a mouse or a keyboard of the host computer, so that the selected operation will be executed. After replacing the corresponding ink cartridge by a new one according to the message shown in Figure 18, if the execution button is selected, it is determined in step S116 of Figure 2 that replacement of the ink cartridge has been performed, and the program then goes to step S301 shown in Figure 3. In the case where the stop button is selected in the status window of Figure 18, replacement of the ink cartridge in step S116 of Figure 2 is not performed, and it is determined in step S117 that an "abort" command has been issued, and generation of printing information is canceled and the program returns to step S102 of Figure 2 at which the program waits until a command telling that generation of printing information should be started is issued again.

In the case where the program has branched to step S301, a message 4 is displayed. The message 4 is displayed in a status window on the display screen as shown in Figure 22. As shown in Figure 22, the status window contains a message telling that the printer will start cleaning the print head, and also contains "execute" and "stop" buttons. Either button may be selected via input means such as a mouse or a keyboard of the host computer, so that the selected operation will be executed. In the case where the stop button is selected, it is determined in step S302 of Figure 3 that a forced aborting command has been issued, and thus the generation of printing information is canceled and the program returns to step S102 of Figure 2 and waits until a command telling that generation of printing information should be started is issued again. Alternatively, in the case where it has been determined in the above step S302 of Figure 3 that a forced aborting command has been issued, the program may return to step S115 of Figure 2 so that the message shown in Figure 18 will be displayed again in the status window. If the "execute" button is selected in the status window of Figure 22, it is concluded in step S303 of Figure 3 that an "execute" command has been issued, and thus in step S304 a cleaning execution command is sent to the printer. On reception of the cleaning execution command, the printer sets the cleaning execution flag to 1 and starts the cleaning operation. When the cleaning operation is completed, the printer immediately resets the cleaning execution flag to 0. In step S305, if a cleaning completion signal indicating that the cleaning execution flag = 0 is received, the no-ink flag corresponding to the color of the cleaned ink cartridge is reset. Then in step S307, the generation of printing information is started again, and the program goes to step S105 of Figure 2. Alternatively, in the above step S306 of Figure 3, the flag may be reset by the printer itself instead of the host computer.

In step S105 of Figure 2, if it is concluded that the remaining ink flag is 1 which indicates that the amount of ink remaining in an ink cartridge is not enough, then the program goes to step S118 at which the generation of printing information is temporarily stopped. Then in step S119, a message 3 is displayed. The message 3 is displayed in a status window on the display screen as shown in Figure 19. As shown in Figure 19, the status window contains a message telling that the amount of remaining ink is not enough and thus printing will be stopped before completion if the amount of data to be printed is too large, and also information of the color of that ink. The status window also contains "execute" and "stop" buttons. Either button may be selected via input means such as a mouse or a keyboard of the host computer, so that the selected operation will be executed. After replacing the corresponding ink cartridge by a new one according to the message shown in Figure 19, if the execution button is selected, it is determined in step S120 of Figure 2 that replacement of the ink cartridge is complete, and the program then goes to step S301 shown in Figure 3. In the case where the stop button is selected in the status window of Figure 19, no ink cartridge is replaced in step S120 of Figure 2, and it is determined in step S121 that a "neglect" command has been issued, and the program goes to step S122 to start generation of printing information again. The program then goes to step S106. Even in the case where only a small

amount of ink remains, printing may be performed on a few further pages if the image to be printed has a low dot density as in the case of a usual document of which almost all portions are in the form of characters. Therefore, the generation of printing information is not forced to be canceled in this case and the user can select either whether the ink cartridge is immediately replaced by a new one or printing is performed without replacement of the ink cartridge.

5 In the case where the program has branched to step S301, a message 4 is displayed. The message 4 is displayed in a status window on the display screen as shown in Figure 22. As shown in Figure 22, the status window contains a message telling that the printer will start cleaning the print head, and also contains "execute" and "stop" buttons. Either button may be selected via input means such as a mouse or a keyboard of the host computer, so that the selected operation will be executed. In the case where the stop button is selected, it is determined in step S302 of Figure 3 that 10 a forced aborting command has been issued, and thus the generation of printing information is canceled and the program returns to step S102 of Figure 2 and waits until a command telling that generation of printing information should be started is issued again. Alternatively, in the case where it has been determined in the above step S302 of Figure 3 that 15 a forced aborting command has been issued, the program may return to step S119 of Figure 2 so that the message shown in Figure 17 will be displayed again in the status window. If the "execute" button is selected in the status window of Figure 22, it is concluded in step S303 of Figure 3 that an "execute" command has been issued, and thus in step S304 a cleaning execution command is sent to the printer. On reception of the cleaning execution command, the printer sets the cleaning execution flag to 1 and starts the cleaning operation. When the cleaning operation is completed, the printer immediately resets the cleaning execution flag to 0. In step S305, if a cleaning completion signal indicating that 20 the cleaning execution flag = 0 is received, the remaining ink flag corresponding to the color of the cleaned ink cartridge is reset. Then in step S307, the generation of printing information is started again, and the program goes to step S106 of Figure 2. Alternatively, in the above step S306 of Figure 3, the flag may be reset by the printer itself instead of the host computer.

25 The above-described process of checking the flags in the steps S103, S104, and S105 and the succeeding process according to the result of the checking are performed repeatedly until it is concluded in step S108 of Figure 2 that all image data (printing information) has been output. If it is concluded in step S108 that all image data (printing information) has been output, the program goes to step S109. If an "end" command is not issued in step S109, then the program returns to step S109 and waits for another command telling that generation of printing information should be started.

30 In this embodiment, the host computer can know the printer status regarding the presence of ink cartridges, the lack of ink, and the amount of remaining ink. This provides a great advantage particularly when the printer is installed at a location rather far from the host computer or when the printer is shared by a plurality of computers via a network.

## EMBODIMENT 2

35 Referring to the flowcharts shown in Figures 3 and 4, the process of another embodiment according to the present invention will be described below.

In step S401 shown in Figure 4, the program begins with receiving status information from the printer. In step S402, if a command is received which indicates that generation of printing information should be started, then in step S403 an original image is analyzed to determine which ink color should be used. In general, the printer driver issues a command to the OS system to convert the printing information generated by application software into image data in a form that 40 matches the resolution of the printer. If the printer has a high resolution such as 360 dpi, the development of image data and the analysis of the colors impose a heavy load on the processing. In such a case, an original image is developed with a low resolution such as 73 dpi first, and the colors of the original image are analyzed, and finally high-resolution development and analysis are performed so as to improve the processing speed. This also reduces the memory capacity requirement.

45 Then, in step S404, the program checks the ink cartridge flag associated with the color to be used. If the ink cartridge flag associated with the color to be used is 0, that is, an ink cartridge of the color to be used is mounted on the printer, then the program goes to step S405. In step S405, the program checks the no-ink flag associated with the color to be used. If the no-ink flag associated with the color to be used is 0, that is, there is ink in the ink cartridge of the color to be used, then the program goes to step S406. In step S406, the program checks the remaining ink flag associated with the color to be used. If the remaining ink flag associated with the color to be used is 0, that is, the remaining amount of ink of the color to be used is enough, then the program goes to step S407. In step S407, printing information is generated by converting image information into a form suitable for printing. Then in step S408 the generated printing information is output to the printer band by band.

55 If it is concluded in step S404 that the ink cartridge flag associated with the color to be used is 1, that is, the ink cartridge of the color to be used is not mounted on the printer, then the program goes to step S411 and the generation of printing information is temporarily stopped. Then in step S412, a message 1 is displayed. As in the case of Embodiment 1, the message 1 is displayed in a status window on the display screen as shown in Figure 17. As shown in Figure 17, the status window contains a message telling that a particular ink cartridge is not mounted on the printer and also telling the color of that cartridge. The status window also contains "execute" and "stop" buttons. Either button may be selected

via input means such as a mouse or a keyboard of the host computer, so that the selected operation will be executed. After mounting an ink cartridge according to the message shown in Figure 17, if the execution button is selected, it is determined in step S413 shown in Figure 4 that replacement of an ink cartridge has been performed, and the program then goes to step S301 shown in Figure 3. In the case where the stop button is selected in the status window of Figure 17, no ink cartridge is replaced in step S413 of Figure 4, and it is determined in step S414 that a forced aborting command has been issued, and thus the generation of printing information is canceled and the program returns to step S402 and waits until a command telling that generation of printing information should be started is issued again.

In the case where the program has branched to step S301, a message 4 is displayed. As in the case of Embodiment 1, the message 4 is displayed in a status window on the display screen as shown in Figure 22. As shown in Figure 22, the status window contains a message telling that the printer will start cleaning the print head, and also contains "execute" and "stop" buttons. Either button may be selected via input means such as a mouse or a keyboard of the host computer, so that the selected operation will be executed. In the case where the stop button is selected, it is determined in step S302 of Figure 3 that a forced aborting command has been issued, and thus the generation of printing information is canceled and the program returns to step S402 of Figure 4 and waits until a command telling that generation of printing information should be started is issued again. Alternatively, in the case where it has been determined in the above step S302 of Figure 3 that a forced aborting command has been issued, the program may return to step S412 of Figure 4 so that the message shown in Figure 17 will be displayed again in the status window. If the "execute" button is selected in the status window of Figure 22, it is concluded in step S303 of Figure 3 that an "execute" command has been issued, and thus in step S304 a cleaning execution command is sent to the printer. On reception of the cleaning execution command, the printer sets the cleaning execution flag to 1 and starts the cleaning operation. When the cleaning operation is completed, the printer immediately resets the cleaning execution flag to 0. In step S305, if a cleaning completion signal indicating that the cleaning execution flag = 0 is received, the ink cartridge flag corresponding to the color of the cleaned ink cartridge is reset. Then in step S307, the generation of printing information is started again, and the program goes to step S405 of Figure 4. Alternatively, in the above step S306 of Figure 3, the flag may be reset by the printer itself instead of the host computer.

On the other hand, if it is concluded in step S405 of Figure 4 that the no-ink flag associated with the color to be used is 1, that is, there is no ink of the color to be used in the ink cartridge, then the program goes to step S415 at which the generation of printing information is temporarily stopped. Then in step S416, a message 2 is displayed. As in the case of Embodiment 1 described above, the message 2 is also displayed in a status window on the display screen as shown in Figure 18. As shown in Figure 18, the status window contains a message telling that a particular ink cartridge has no ink in it and also telling the ink color of that cartridge. The status window also contains "execute" and "stop" buttons. Either button may be selected via input means such as a mouse or a keyboard of the host computer, so that the selected operation will be executed. After replacing the corresponding ink cartridge by a new one according to the message shown in Figure 18, if the execution button is selected, it is determined in step S417 of Figure 4 that replacement of the ink cartridge has been performed, and the program then goes to step S301 shown in Figure 3. In the case where the stop button is selected in the status window of Figure 18, no ink cartridge is replaced in step S417 of Figure 4, and it is determined in step S418 that a forced aborting command has been issued, and thus the generation of printing information is canceled and the program returns to step S402 and waits until a command telling that generation of printing information should be started is issued again.

In the case where the program has branched to step S301, a message 4 is displayed. As in the case of Embodiment 1 described above, the message 4 is also displayed in a status window on the display screen as shown in Figure 22. As shown in Figure 22, the status window contains a message telling that the printer will start cleaning the print head, and also contains "execute" and "stop" buttons. Either button may be selected via input means such as a mouse or a keyboard of the host computer, so that the selected operation will be executed. In the case where the stop button is selected, it is determined in step S302 that a forced aborting command has been issued, and thus the generation of printing information is canceled and the program returns to step S402 of Figure 4 and waits until a command telling that generation of printing information should be started is issued again. Alternatively, in the case where it has been determined in the above step S302 of Figure 3 that a forced aborting command has been issued, the program may return to step S416 of Figure 4 so that the message shown in Figure 18 will be displayed again in the status window. If the "execute" button is selected in the status window of Figure 22, it is concluded in step S303 of Figure 3 that an "execute" command has been issued, and thus in step S304 a cleaning execution command is sent to the printer. On reception of the cleaning execution command, the printer sets the cleaning execution flag to 1 and starts the cleaning operation. When the cleaning operation is completed, the printer immediately resets the cleaning execution flag to 0. In step S305, if a cleaning completion signal indicating that the cleaning execution flag = 0 is received, the no-ink flag corresponding to the color of the cleaned ink cartridge is reset. Then in step S307, the generation of printing information is started again, and the program goes to step S406 of Figure 4. Alternatively, in the above step S306, the flag may be reset by the printer itself instead of the host computer.

In step S406, if it is concluded that the remaining ink flag associated with the color to be used is 1, that is the amount of ink of the color to be used remaining in the ink cartridge is not enough, then the program goes to step S419 at which

the generation of printing information is temporarily stopped. Then in step S420, a message 3 is displayed. As in the case of Embodiment 1 described above, the message 3 is also displayed in a status window on the display screen as shown in Figure 19. As shown in Figure 19, the status window contains a message telling that the amount of remaining ink is not enough and thus printing will be stopped before completion if the amount of data to be printed is too large, and also telling the color of that ink. The status window also contains "execute" and "stop" buttons. Either button may be selected via input means such as a mouse or a keyboard of the host computer, so that the selected operation will be executed. After replacing the corresponding ink cartridge by a new one according to the message shown in Figure 19, if the execution button is selected, it is determined in step S421 of Figure 4 that replacement of the ink cartridge is complete, and the program then goes to step S301 shown in Figure 3. In the case where the stop button is selected in the status window of Figure 19, no ink cartridge is replaced in step S421 of Figure 4, and it is determined in step S422 that a "neglect" command has been issued, and the program goes to step S423 to start generation of printing information again. The program then goes to step S407. Even in the case where only a small amount of ink remains, printing may be performed on a few further pages if the image to be printed has a low dot density as in the case of a usual document, almost all portions of which are in the form of characters. Therefore, the generation of printing information is not forced to be canceled in this case and the user can select whether the ink cartridge is immediately replaced by a new one or printing is performed without replacement of the ink cartridge.

In the case where the program has branched to step S301, a message 4 is displayed. As in the case of Embodiment 1 described above, the message 4 is also displayed in a status window on the display screen as shown in Figure 22. As shown in Figure 22, the status window contains a message telling that the printer will start cleaning the print head, and also contains "execute" and "stop" buttons. Either button may be selected via input means such as a mouse or a keyboard of the host computer, so that the selected operation will be executed. In the case where the stop button is selected, it is determined in step S302 of Figure 3 that a forced aborting command has been issued, and thus the generation of printing information is canceled and the program returns to step S402 of Figure 4 and waits until a command telling that generation of printing information should be started is issued again. Alternatively, in the case where it has been determined in the above step S302 of Figure 3 that a forced aborting command has been issued, the program may return to step S420 of Figure 4 so that the message shown in Figure 17 will be displayed again in the status window. If the "execute" button is selected in the status window of Figure 22, it is concluded in step S303 of Figure 3 that an "execute" command has been issued, and thus in step S304 a cleaning execution command is sent to the printer. On reception of the cleaning execution command, the printer sets the cleaning execution flag to 1 and starts the cleaning operation. When the cleaning operation is completed, the printer immediately resets the cleaning execution flag to 0. In step S305, if a cleaning completion signal indicating that the cleaning execution flag = 0 is received, the remaining ink flag corresponding to the color of the cleaned ink cartridge is reset. Then in step S307, the generation of printing information is started again, and the program goes to step S407 of Figure 4. Alternatively, in the above step S306 of Figure 3, the flag may be reset by the printer itself instead of the host computer.

The above-described process of checking the flags in the steps S404, S405, and S406 and the succeeding process according to the result of the checking are performed repeatedly until it is concluded in step S409 of Figure 4 that all image data (printing information) has been output. If it is concluded in step S409 that all image data (printing information) has been output, the program goes to step S410. If an "end" command is not issued in step S410, then the program returns to step S402 and waits for another command telling that generation of printing information should be started.

As in the previous embodiment, the host computer can know the printer status regarding the presence of ink cartridges, the lack of ink, and the amount of remaining ink. This feature of the present embodiment also provides a great advantage particularly when the printer is installed at a location rather far from the host computer or when the printer is shared by a plurality of computers via a network.

Furthermore, in this embodiment, because status detection regarding the ink cartridge flag, no-ink flag, and remaining ink flag, is performed only for the colors which are actually used in the printing operation, the status detection needs a short time and thus the overall printing process speed is also improved. Furthermore, the printing operation is not stopped unnecessarily by the status information regarding the colors which are not used in the printing operation.

### EMBODIMENT 3

Referring to the flowcharts shown in Figures 3, 5, 6, 7, and 8, the process of still another embodiment according to the present invention will be described below.

In step S501 shown in Figure 5, the program begins with receiving status information from the printer. In step S502, if a command is received which indicates that generation of printing information should be started, then in step S503 the program determines the color mode to be used. The color mode may be designated by means of selecting operation via the control panel of the printer itself or via a menu of the printer driver displayed on the screen of the host computer. When the color mode is selected via the control panel of the printer, the printer itself acquires color mode status information wherein the color mode status is represented by the color mode flag in such a manner that the monochrome printing mode is denoted by a value of 0 in the color mode flag and the color printing mode is denoted by 1.

The program then goes to step S504. If it is determined that the current color mode is in the monochrome printing mode, then the program goes to step S505. In step S505, only the ink cartridge flag associated with black ink is examined. If the ink cartridge flag associated with black ink is 0, that is, an ink cartridge of black ink is mounted on the printer, then the program goes to step S506. In step S506, only the no-ink flag associated with black ink is examined. If the no-ink flag associated with black ink is 0, that is, there is ink in the ink cartridge for black ink, then the program goes to step S701. In step S701, only the remaining ink flag associated with black ink is examined. If the remaining ink flag associated with black ink is 0, that is, the remaining amount of black ink is enough, then the program goes to step S702. In step S702, printing information is generated by converting image information into a form suitable for printing band by band. Then in step S703 the generated printing information is output to the printer band by band.

If it is concluded in step S505 of Figure 5 that the ink cartridge flag associated with black ink is 1, that is, the ink cartridge of black ink is not mounted on the printer, then the program goes to step S507 and the generation of printing information is temporarily stopped. Then in step S508, a message 1 is displayed. As in the case of Embodiment 1 described above, the message 1 is also displayed in a status window on the display screen as shown in Figure 17. As shown in Figure 17, the status window contains a message telling that an ink cartridge is not mounted on the printer and also telling the color of that cartridge. The status window also contains "execute" and "stop" buttons. Either button may be selected via input means such as a mouse or a keyboard of the host computer, so that the selected operation will be executed. After mounting an ink cartridge according to the message shown in Figure 17, if the execution button is selected, it is determined in step S509 that replacement of an ink cartridge has been performed, and the program then goes to step S301 shown in Figure 3. In the case where the stop button is selected in the status window of Figure 17, no ink cartridge is replaced in step S509, and it is determined in step S510 that an "abort" command has been issued, and thus the generation of printing information is canceled. The program then returns to step S502 and waits for a command indicating that generation of printing information should be started again.

In the case where the program has branched to step S301, message 4 is displayed. As in the case of Embodiment 1 described above, the message 4 is also displayed in a status window on the display screen as shown in Figure 22. As shown in Figure 22, the status window contains a message telling that the printer will start cleaning the print head, and also contains "execute" and "stop" buttons. Either button may be selected via input means such as a mouse or a keyboard of the host computer, so that the selected operation will be executed. In the case where the stop button is selected, it is determined in step S302 of Figure 3 that a forced aborting command has been issued, and thus the generation of printing information is canceled and the program returns to step S502 of Figure 5 and waits until a command telling that generation of printing information should be started is issued again. Alternatively, in the case where it has been determined in the above step S302 of Figure 3 that a forced aborting command has been issued, the program may return to step S508 of Figure 5 so that the message shown in Figure 15 will be displayed again in the status window. If the "execute" button is selected in the status window of Figure 19, it is concluded in step S303 of Figure 3 that an "execute" command has been issued, and thus in step S304 a cleaning execution command is sent to the printer. On reception of the cleaning execution command, the printer sets the cleaning execution flag to 1 and starts the cleaning operation. When the cleaning operation is completed, the printer immediately resets the cleaning execution flag to 0. In step S305, if a cleaning completion signal indicating that the cleaning execution flag = 0 is received, the no-ink flag associated with black ink is reset. Then in step S307, the generation of printing information is started again, and the program goes to step S506 of Figure 5. Alternatively, in the above step S306 of Figure 3, the flag may be reset by the printer itself instead of the host computer.

On the other hand, if it is concluded in step S506 of Figure 5 that the no-ink flag associated with black ink is 1, that is, there is no ink in the black ink cartridge, then the program goes to step S511 at which the generation of printing information is temporarily stopped. Then in step S511, a message 2 is displayed. As in the case of Embodiment 1 described above, the message 2 is also displayed in a status window on the display screen as shown in Figure 18. As shown in Figure 18, the status window contains a message telling that some ink cartridge has no ink in it and also telling the ink color of that cartridge. The status window also contains "execute" and "stop" buttons. Either button may be selected via input means such as a mouse or a keyboard of the host computer, so that the selected operation will be executed. After replacing the corresponding ink cartridge by a new one according to the message shown in Figure 18, if the execution button is selected, it is determined in step S513 of Figure 5 that replacement of the ink cartridge has been performed, and the program then goes to step S301 shown in Figure 3. In the case where the stop button is selected in the status window of Figure 18, ink cartridge replacement is not performed in step S513, and it is determined in step S514 that an "abort" command "has been issued, and thus the generation of printing information is canceled. The program then returns to step S502 and waits for a command indicating that generation of printing information should be started again.

In the case where the program has branched to step S301, a message 4 is displayed. As in the case of Embodiment 1 described above, the message 4 is also displayed in a status window on the display screen as shown in Figure 22. As shown in Figure 22, the status window contains a message telling that the printer will start cleaning the print head, and also contains "execute" and "stop" buttons. Either button may be selected via input means such as a mouse or a keyboard of the host computer, so that the selected operation will be executed. In the case where the stop button is

selected, it is determined in step S302 of Figure 3 that a forced aborting command has been issued, and thus the generation of printing information is canceled and the program returns to step S502 at which the program waits until a command telling that generation of printing information should be started is issued again. Alternatively, in the case where it has been determined in the above step S302 of Figure 3 that a forced aborting command has been issued, the program 5 may return to step S512 of Figure 5 so that the message shown in Figure 18 will be displayed again in the status window. If the "execute" button is selected in the status window of Figure 19, it is concluded in step S303 of Figure 3 that an "execute" command has been issued, and thus in step S304 a cleaning execution command is sent to the printer. On 10 reception of the cleaning execution command, the printer sets the cleaning execution flag to 1 and starts the cleaning operation. When the cleaning operation is completed, the printer immediately resets the cleaning execution flag to 0. In step S305, if a cleaning completion signal indicating that the cleaning execution flag = 0 is received, the no-ink flag associated with black ink is reset. Then in step S307, the generation of printing information is started again, and the program goes to step S701 of Figure 7. Alternatively, in the above step S306 of Figure 3, the flag may be reset by the printer itself instead of the host computer.

In step S701 of Figure 7, if it is concluded that the remaining ink flag associated with black ink is 1, that is the 15 remaining amount of black ink in the ink cartridge is not enough, then the program goes to step S706 at which the generation of printing information is temporarily stopped. Then in step S707, a message 3 is displayed. As in the case of Embodiment 1 described above, the message 3 is also displayed in a status window on the display screen as shown in Figure 19. As shown in Figure 19, the status window contains a message telling that the amount of remaining ink is not enough and thus printing will be stopped before completion if the amount of data to be printed is too large, and also 20 telling the color of that ink. The status window also contains "execute" and "stop" buttons. Either button may be selected via input means such as a mouse or a keyboard of the host computer, so that the selected operation will be executed. After replacing the corresponding ink cartridge by a new one according to the message shown in Figure 19, if the 25 execution button is selected, it is determined in step S708 that replacement of the ink cartridge has been performed, and the program then goes to step S301 shown in Figure 3. In the case where the stop button is selected in the status window of Figure 19, ink cartridge replacement is not performed in step S708, and it is determined in step S709 that an "abort" command has been issued, and the program goes to step S710 to start generation of printing information again. The program then goes to step S702. Even in the case where only a small amount of ink remains, printing may be 30 performed on a few further pages if the image to be printed has a low dot density as in the case of a usual document almost all portions of which are in the form of characters. Therefore, the generation of printing information is not forced to be canceled in this case and the user can select whether the ink cartridge is immediately replaced by a new one or printing is performed without replacement of the ink cartridge.

In the case where the program has branched to step S301, a message 4 is displayed. As in the case of Embodiment 1 described above, the message 4 is also displayed in a status window on the display screen as shown in Figure 22. As shown in Figure 22, the status window contains a message telling that the printer will start cleaning the print head, 35 and also contains "execute" and "stop" buttons. Either button may be selected via input means such as a mouse or a keyboard of the host computer, so that the selected operation will be executed. In the case where the stop button is selected, it is determined in step S302 of Figure 3 that a forced aborting command has been issued, and thus the generation of printing information is canceled and the program returns to step S502 at which the program waits until a command telling that generation of printing information should be started is issued again. Alternatively, in the case where 40 it has been determined in the above step S302 of Figure 3 that a forced aborting command has been issued, the program may return to step S707 of Figure 7 so that the message shown in Figure 19 will be displayed again in the status window. If the "execute" button is selected in the status window of Figure 22, it is concluded in step S303 of Figure 3 that an "execute" command has been issued, and thus in step S304 a cleaning execution command is sent to the printer. On 45 reception of the cleaning execution command, the printer sets the cleaning execution flag to 1 and starts the cleaning operation. When the cleaning operation is completed, the printer immediately resets the cleaning execution flag to 0. In step S305, if a cleaning completion signal indicating that the cleaning execution flag = 0 is received, the remaining ink flag associated with black ink is reset. Then in step S307 of Figure 3, the generation of printing information is started again, and the program goes to step S702 of Figure 7. Alternatively, in the above step S306 of Figure 3, the flag may 50 be reset by the printer itself instead of the host computer.

The above-described process of checking the flags in steps S505, S506, and S507 and the succeeding process according to the result of the checking are performed repeatedly until it is concluded in step S704 of Figure 7 that all 55 image data (printing information) has been output. If it is concluded in step S701 of Figure 7 that all image data (printing information) has been output, the program goes to step S705. If an "end" command is not issued in step S705, then the program returns to step S502 and waits for another command telling that generation of printing information should be started.

On the other hand, if it is concluded in step S504 that the current color mode is in the color printing mode, then the program goes to step S601 of Figure 6. In step S601, the program checks all the ink cartridge flags associated with individual colors. If the ink cartridge flag is 0, that is, all ink cartridges are mounted on the printer, then the program goes to step S602. In step S602, the program checks all the no-ink flags associated with individual colors. If all the no-ink

flags are 0, that is, there is ink in all the ink cartridges, then the program goes to step S711 of Figure 8. In step S711, the program checks all the remaining ink flags associated with individual colors. If all the remaining ink flags are 0, that is, the remaining amounts of ink are much enough, then the program goes to step S712. In step S712, printing information is generated by converting image data into a form suitable for printing. Then in step S713 the generated image data (printing information) is output to the printer.

If it is concluded in step S601 that the ink cartridge flag associated with a particular color is 1, that is, an ink cartridge of a particular color is not mounted on the printer, then the program goes to step S603 and the generation of printing information is temporarily stopped. Then in step S604, a message 1 is displayed. As in the case of Embodiment 1 described above, the message 1 is also displayed in a status window on the display screen as shown in Figure 17. As shown in Figure 17, the status window contains a message telling that some ink cartridge is not mounted on the printer and also telling the color of that cartridge. The status window also contains "execute" and "stop" buttons. Either button may be selected via input means such as a mouse or a keyboard of the host computer, so that the selected operation will be executed. After mounting an ink cartridge according to the message shown in Figure 17, if the execution button is selected, it is determined in step S605 shown in Figure 6 that replacement of an ink cartridge has been performed, and the program then goes to step S301 shown in Figure 3. In the case where the stop button is selected in the status window of Figure 17, no ink cartridge is replaced in step S605 of Figure 6, and it is determined in step S606 that a forced aborting command has been issued, and thus the generation of printing information is canceled and the program returns to step S502 of Figure 5 and waits until a command telling that generation of printing information should be started is issued again.

In the case where the program has branched to step S301, a message 4 is displayed. As in the case of Embodiment 1 described above, the message 4 is also displayed in a status window on the display screen as shown in Figure 22. As shown in Figure 22, the status window contains a message telling that the printer will start cleaning the print head, and also contains "execute" and "stop" buttons. Either button may be selected via input means such as a mouse or a keyboard of the host computer, so that the selected operation will be executed. In the case where the stop button is selected, it is determined in step S302 of Figure 3 that a forced aborting command has been issued, and thus the generation of printing information is canceled and the program returns to step S502 of Figure 5 and waits until a command telling that generation of printing information should be started is issued again. Alternatively, in the case where it has been concluded in the above step S302 of Figure 3 that a forced aborting command has been issued, the program may return to step S604 of Figure 6 so that the message shown in Figure 17 will be displayed again in the status window. If the "execute" button is selected in the status window of Figure 22, it is concluded in step S303 of Figure 3 that an "execute" command has been issued, and thus in step S304 a cleaning execution command is sent to the printer. On reception of the cleaning execution command, the printer sets the cleaning execution flag to 1 and starts the cleaning operation. When the cleaning operation is completed, the printer immediately resets the cleaning execution flag to 0. In step S305, if a cleaning completion signal indicating that the cleaning execution flag = 0 is received, the remaining ink flag associated with the corresponding color is reset. Then in step S307, the generation of printing information is started again, and the program goes to step S602 of Figure 6. Alternatively, in the above step S306 of Figure 3, the flag may be reset by the printer itself instead of the host computer.

On the other hand, if it is concluded in step S602 of Figure 6 that the no-ink flag associated with some color is 1, that is, there is no ink in some ink cartridge, then the program goes to step S607 at which the generation of printing information is temporarily stopped. Then in step S608, a message 2 is displayed. As in the case of Embodiment 1 described above, the message 2 is also displayed in a status window on the display screen as shown in Figure 18. As shown in Figure 18, the status window contains a message telling that a particular ink cartridge has no ink in it and also telling the ink color of that cartridge. The status window also contains "execute" and "stop" buttons. Either button may be selected via input means such as a mouse or a keyboard of the host computer, so that the selected operation will be executed. After mounting an ink cartridge according to the message shown in Figure 18, if the execution button is selected, it is determined in step S609 that replacement of an ink cartridge has been performed, and the program then goes to step S301 shown in Figure 3. In the case where the stop button is selected in the status window of Figure 18, ink cartridge replacement is not performed in step S609, and it is determined in step S610 that a forced aborting command has been issued, and thus the generation of printing information is canceled and the program returns to step S502 of Figure 5 and waits until a command telling that generation of printing information should be started is issued again.

In the case where the program has branched to step S301, a message 4 is displayed. As in the case of Embodiment 1 described above, the message 4 is also displayed in a status window on the display screen as shown in Figure 22. As shown in Figure 22, the status window contains a message telling that the printer will start cleaning the print head, and also contains "execute" and "stop" buttons. Either button may be selected via input means such as a mouse or a keyboard of the host computer, so that the selected operation will be executed. In the case where the stop button is selected, it is determined in step S302 of Figure 3 that a forced aborting command has been issued, and thus the generation of printing information is canceled and the program returns to step S502 of Figure 5 and waits until a command telling that generation of printing information should be started is issued again. Alternatively, in the case where it has been concluded in the above step S302 of Figure 3 that a forced aborting command has been issued, the program may

return to step S608 of Figure 6 so that the message shown in Figure 18 will be displayed again in the status window. If the "execute" button is selected in the status window of Figure 22, it is concluded in step S303 of Figure 3 that an "execute" command has been issued, and thus in step S304 a cleaning execution command is sent to the printer. On reception of the cleaning execution command, the printer sets the cleaning execution flag to 1 and starts the cleaning operation. When the cleaning operation is completed, the printer immediately resets the cleaning execution flag to 0. In step S305, if a cleaning completion signal indicating that the cleaning execution flag = 0 is received, the no-ink flag corresponding to the color of the cleaned ink cartridge is reset. Then in step S307, the generation of printing information is started again, and the program goes to step S711 of Figure 8. Alternatively, in the above step S306 of Figure 3, the flag may be reset by the printer itself instead of the host computer.

In step S711 of Figure 8, if it is concluded that a particular remaining ink flag is 1, that is the remaining amount of ink in a particular ink cartridge is not enough, then the program goes to step S716 at which the generation of printing information is temporarily stopped. Then in step S717, a message 3 is displayed. As in the case of Embodiment 1 described above, the message 3 is also displayed in a status window on the display screen as shown in Figure 19. As shown in Figure 19, the status window contains a message telling that the remaining amount of ink is not enough and thus printing will be stopped before completion if the amount of data to be printed is too large, and also telling the color of that ink. The status window also contains "execute" and "stop" buttons. Either button may be selected via input means such as a mouse or a keyboard of the host computer, so that the selected operation will be executed. After replacing the corresponding ink cartridge by a new one according to the message shown in Figure 19, if the execution button is selected, it is determined in step S718 of Figure 8 that replacement of the ink cartridge is complete, and the program then goes to step S301 shown in Figure 3. In the case where the stop button is selected in the status window of Figure 19, ink cartridge replacement is not performed in step S718, and it is determined in step S719 that an "abort" command has been issued, and the program goes to step S720 to start generation of printing information again. The program then goes to step S712. Even in the case where only a small amount of ink remains, printing may be performed on a few further pages if the image to be printed has a low dot density as in the case of a usual document, almost all portions of which are in the form of characters. Therefore, the generation of printing information is not forced to be canceled in this case and the user can select whether the ink cartridge is immediately replaced by a new one or printing is performed without replacement of the ink cartridge.

In the case where the program has branched to step S301, a message 4 is displayed. As in the case of Embodiment 1 described above, the message 4 is also displayed in a status window on the display screen as shown in Figure 22. As shown in Figure 22, the status window contains a message telling that the printer will start cleaning the print head, and also contains "execute" and "stop" buttons. Either button may be selected via input means such as a mouse or a keyboard of the host computer, so that the selected operation will be executed. In the case where the stop button is selected, it is determined in step S302 of Figure 3 that a forced aborting command has been issued, and thus the generation of printing information is canceled and the program returns to step S502 of Figure 5 and waits until a command telling that generation of printing information should be started is issued again. Alternatively, in the case where it has been concluded in the above step S302 of Figure 3 that a forced aborting command has been issued, the program may return to step S717 of Figure 8 so that the message shown in Figure 19 will be displayed again in the status window. If the "execute" button is selected in the status window of Figure 22, it is concluded in step S303 of Figure 3 that an "execute" command has been issued, and thus in step S304 a cleaning execution command is sent to the printer. On reception of the cleaning execution command, the printer sets the cleaning execution flag to 1 and starts the cleaning operation. When the cleaning operation is completed, the printer immediately resets the cleaning execution flag to 0. In step S305, if a cleaning completion signal indicating that the cleaning execution flag = 0 is received, the remaining ink flag corresponding to the color of the cleaned ink cartridge is reset. Then in step S307, the generation of printing information is started again, and the program goes to step S712 of Figure 8. Alternatively, in the above step S306 of Figure 3, the flag may be reset by the printer itself instead of the host computer.

The above-described process of checking the flags in steps S601 and S602 of Figure 6 and step S711 of Figure 8 and the succeeding process according to the result of the checking are performed repeatedly until it is concluded in step S714 of Figure 8 that all image data (printing information) has been output. If it is concluded in step S714 that all image data (printing information) has been output, the program goes to steps S715. If an "end" command is not issued in step S715, then the program returns to step S502 of Figure 5 and waits for another command telling that generation of printing information should be started.

As in the previous embodiments, the host computer can know the printer status regarding the presence of ink cartridges, the lack of ink, and the amount of remaining ink. This feature of the present embodiment also provides a great advantage particularly when the printer is installed at a location rather far from the host computer or when the printer is shared by a plurality of computers via a network.

Furthermore in the present embodiment, the detection of the ink cartridge flags, no-ink flags, and remaining ink flags is performed depending on the designated color mode, and thus the detection time is reduced when operating in the monochrome printing mode in which only black ink is used, which results in an improvement in the printing speed. This also prevents the printing operation from being unnecessarily stopped by status information regarding an ink color

which is not used. Furthermore, in this embodiment it is not required to determine which color should be used in printing, and therefore the processing load associated with handling of image data is reduced.

#### EMBODIMENT 4

5

Referring now to the flowcharts shown in Figures 3, 5, 6, 9 and 10, the process of a fourth embodiment according to the present invention will be described below.

In step S501 shown in Figure 5, the program begins with receiving status information from the printer. In step S502, if a command is received which indicates that generation of printing information should be started, then in step S503 the program determines the color mode to be used. The color mode may be designated by means of selecting operation via the control panel of the printer itself or via a menu of the printer driver displayed on the screen of the host computer. When the color mode is selected via the control panel of the printer, the printer itself acquires color mode status information wherein the color mode status is represented by the color mode flag in such a manner that the monochrome printing mode is denoted by a value of 0 in the color mode flag and the color printing mode is denoted by 1.

The program then goes to step S504. If it is determined that the current color mode is in the monochrome printing mode, then the program goes to step S505. In step S505, only the ink cartridge flag associated with black ink is examined. If the ink cartridge flag associated with black ink is 0, that is, an ink cartridge of black ink is mounted on the printer, then the program goes to step S506. In step S506, only the no-ink flag associated with black ink is examined. If the no-ink flag associated with black ink is 0, that is, there is ink in the black ink cartridge, then the program goes to step S801. In step S801, only the remaining ink flag associated with black ink is examined. If the remaining ink flag associated with black ink is 0, that is, the remaining amount of black ink is enough, then the program goes to step S802. In step S802, printing information is generated by converting image data into a form suitable for printing. Then in step S803 the generated image data (printing information) is output to the printer.

If it is concluded in step S505 of Figure 5 that the ink cartridge flag associated with black ink is 1, that is, the ink cartridge of black ink is not mounted on the printer, then the program goes to step S507 and the generation of printing information is temporarily stopped. Then in step S508, a message 1 is displayed. As in the case of Embodiment 1 described above, the message 1 is also displayed in a status window on the display screen as shown in Figure 17. As shown in Figure 17, the status window contains a message telling that a particular ink cartridge is not mounted on the printer and also telling the color of that cartridge. The status window also contains "execute" and "stop" buttons. Either button may be selected via input means such as a mouse or a keyboard of the host computer, so that the selected operation will be executed. After mounting an ink cartridge according to the message shown in Figure 17, if the execution button is selected, it is determined in step S509 shown in Figure 5 that replacement of an ink cartridge has been performed, and the program then goes to step S301 shown in Figure 3. In the case where the stop button is selected in the status window of Figure 17, ink cartridge replacement is not performed in step S509 of Figure 5, and it is determined in step S510 that an "abort" command has been issued, and the generation of printing information is canceled. In this case, the program returns to step S502 in which the program waits for a command telling that generation of printing information should be started.

In the case where the program has branched to step S301, a message 4 is displayed. As in the case of Embodiment 1 described above, the message 4 is also displayed in a status window on the display screen as shown in Figure 22. As shown in Figure 22, the status window contains a message telling that the printer will start cleaning the print head, and also contains "execute" and "stop" buttons. Either button may be selected via input means such as a mouse or a keyboard of the host computer, so that the selected operation will be executed. In the case where the stop button is selected, it is determined in step S302 of Figure 3 that a forced aborting command has been issued, and thus the generation of printing information is canceled and the program returns to step S502 at which the program waits until a command telling that generation of printing information should be started is issued again. Alternatively, in the case where it has been concluded in the above step S302 of Figure 3 that a forced aborting command has been issued, the program may return to step S508 of Figure 5 so that the message shown in Figure 17 will be displayed again in the status window. If the "execute" button is selected in the status window of Figure 22, it is concluded in step S303 of Figure 3 that an "execute" command has been issued, and thus in step S304 a cleaning execution command is sent to the printer. On reception of the cleaning execution command, the printer sets the cleaning execution flag to 1 and starts the cleaning operation. When the cleaning operation is completed, the printer immediately resets the cleaning execution flag to 0. In step S305, if a cleaning completion signal indicating that the cleaning execution flag = 0 is received, the no-ink flag associated with black ink is reset. Then in step S307 of Figure 3, the generation of printing information is started again, and the program goes to step S506 of Figure 5. Alternatively, in the above step S306 of Figure 3, the flag may be reset by the printer itself instead of the host computer.

On the other hand, if it is concluded in step S506 of Figure 5 that the no-ink flag associated with black ink is 1, that is, there is no ink in the black ink cartridge, then the program goes to step S511 at which the generation of printing information is temporarily stopped. Then in step S511, a message 2 is displayed. As in the case of Embodiment 1 described above, the message 2 is also displayed in a status window on the display screen as shown in Figure 18. As

5 shown in Figure 18, the status window contains a message telling that a particular ink cartridge has no ink in it and also telling the ink color of that cartridge. The status window also contains "execute" and "stop" buttons. Either button may be selected via input means such as a mouse or a keyboard of the host computer, so that the selected operation will be executed. After replacing the corresponding ink cartridge by a new one according to the message shown in Figure 18, if the execution button is selected, it is determined in step S513 of Figure 5 that replacement of the ink cartridge has been performed, and the program then goes to step S301 shown in Figure 3. In the case where the stop button is selected in the status window of Figure 18, no ink cartridge is replaced in step S513 of Figure 5, and it is determined in step S514 that a forced aborting command has been issued, and thus the generation of printing information is canceled and the program returns to step S502 and waits until a command telling that generation of printing information should be started is issued again.

10 In the case where the program has branched to step S301, a message 4 is displayed. As in the case of Embodiment 1 described above, the message 4 is also displayed in a status window on the display screen as shown in Figure 22. As shown in Figure 22, the status window contains a message telling that the printer will start cleaning the print head, and also contains "execute" and "stop" buttons. Either button may be selected via input means such as a mouse or a keyboard of the host computer, so that the selected operation will be executed. In the case where the stop button is selected, it is determined in step S302 of Figure 3 that a forced aborting command has been issued, and thus the generation of printing information is canceled and the program returns to step S502 of Figure 5 and waits until a command telling that generation of printing information should be started is issued again. Alternatively, in the case where it has been concluded in the above step S302 of Figure 3 that a forced aborting command has been issued, the program may 15 return to step S512 of Figure 5 so that the message shown in Figure 18 will be displayed again in the status window. If the "execute" button is selected in the status window of Figure 22, it is concluded in step S303 of Figure 3 that an "execute" command has been issued, and thus in step S304 a cleaning execution command is sent to the printer. On 20 reception of the cleaning execution command, the printer sets the cleaning execution flag to 1 and starts the cleaning operation. When the cleaning operation is completed, the printer immediately resets the cleaning execution flag to 0. In 25 step S305, if a cleaning completion signal indicating that the cleaning execution flag = 0 is received, the no-ink flag associated with black ink is reset. Then in step S307 of Figure 3, the generation of printing information is started again, and the program goes to step S801 of Figure 9. Alternatively, in the above step S306 of Figure 3, the flag may be reset by the printer itself instead of the host computer.

30 In step S801 of Figure 9, if it is concluded that the remaining ink flag associated with black ink is 1, that is the remaining amount of black ink in the ink cartridge is not enough, then the program goes to step S806 at which the generation of printing information is temporarily stopped. Then in step S807, a message 33 is displayed. The message 33 is displayed in a status window on the display screen as shown in Figure 21. As shown in Figure 21, the status window contains a message telling that the amount of remaining ink is not enough and thus printing will be stopped before completion if the amount of data to be printed is too large, and also telling the color of that ink. The status window also 35 contains "execute", "alternative color" and "stop" buttons. Either button may be selected via input means such as a mouse or a keyboard of the host computer, so that the selected operation will be executed. After replacing the corresponding ink cartridge by a new one according to the message shown in Figure 21, if the execution button is selected, it is determined in step S808 of Figure 9 that replacement of the ink cartridge is complete, and the program then goes to step S301 shown in Figure 3. In the case where the stop button is selected in the status window of Figure 21, ink cartridge 40 replacement is not performed in step S808 of Figure 9. In this case it is determined in step S809 that use of an alternative color is not desired, and further in step S810 it is determined that a "neglect" command has been issued. Thus the program goes to step S811 to start generation of printing information again. The program then goes to step S802. Even in the case where only a small amount of ink remains, printing may be performed on a few further pages if the image to be printed has a low dot density as in the case of a usual document, almost all portions of which are in the form of 45 characters. Therefore, the generation of printing information is not forced to be canceled in this case and the user can select whether the ink cartridge is immediately replaced by a new one or printing is performed without replacement of the ink cartridge.

50 In the case where the program has branched to step S301, a message 4 is displayed. As in the case of Embodiment 1 described above, the message 4 is also displayed in a status window on the display screen as shown in Figure 22. As shown in Figure 22, the status window contains a message telling that the printer will start cleaning the print head, and also contains "execute" and "stop" buttons. Either button may be selected via input means such as a mouse or a keyboard of the host computer, so that the selected operation will be executed. In the case where the stop button is selected, it is determined in step S302 of Figure 3 that a forced aborting command has been issued, and thus the generation of printing information is canceled and the program returns to step S502 of Figure 5 and waits until a command 55 telling that generation of printing information should be started is issued again. Alternatively, in the case where it has been concluded in the above step S302 of Figure 3 that a forced aborting command has been issued, the program may return to step S807 of Figure 9 so that the message shown in Figure 21 will be displayed again in the status window. If the "execute" button is selected in the status window of Figure 22, it is concluded in step S303 of Figure 3 that an "execute" command has been issued, and thus in step S304 a cleaning execution command is sent to the printer. On

reception of the cleaning execution command, the printer sets the cleaning execution flag to 1 and starts the cleaning operation. When the cleaning operation is completed, the printer immediately resets the cleaning execution flag to 0. In step S305, if a cleaning completion signal indicating that the cleaning execution flag = 0 is received, the no-ink flag associated with black ink is reset. Then in step S307, the generation of printing information is started again, and the program goes to step S802 of Figure 9. Alternatively, in the above step S306 of Figure 3, the flag may be reset by the printer itself instead of the host computer.

5 In the case where the "alternative color" button is selected according to the message shown in the window of Figure 21, ink cartridge replacement in step S808 of Figure 9 is not performed and it is determined in step S809 that use of an alternative color is requested. In this case, the program goes to step S901 of Figure 11 in which a message 5 is displayed. 10 The message 5 is displayed in a window on the display screen as shown in Figure 23. As shown in Figure 23, the window contains color selection buttons for selecting an alternative color from the group including cyan, magenta, yellow, and gray which is a mixture of the above three colors. The window also contains "execute" and "stop" buttons as well as an instruction message. Either button may be selected via input means such as a mouse or a keyboard of the host computer, so that the selected operation will be executed. If "gray" (mixture of three colors) is selected, printing is performed with 15 a color similar to black which is produced by properly mixing cyan, magenta, and yellow.

Alternative colors are not limited to the above four colors. Red, green, blue, or other colors may also be added to the selection list.

20 In the case where the stop button in the status window of Figure 23 is selected, it is determined in step S905 of Figure 11 that a forced aborting command has been issued, and thus the program goes to step S802 of Figure 9. Alternatively, in the case where the "stop" button is selected in the window of Figure 23, the program may return to step S807 so that the immediately previous message will be displayed again in the status window.

25 In the case where one color is selected from the alternative color group in the window of Figure 23, and the "execute" button is further selected, the selected color is designated as the alternative color in step S902 of Figure 11. The program then goes to step S903. In step S903, the ink cartridge flag, no-ink flag, and the remaining ink flag associated with the designated alternative color are examined. If all these flags are 0, that is, the ink of the designated color is available, then the program goes to step S907 in which the printing mode is switched to an alternative color mode. Then in step 30 S906, the generation of printing information is started again. The program then goes to step S802 of Figure 9. In the alternative color mode, the image data (printing information) processing in step S803 is performed in such a manner that monochrome (black) data is replaced by alternative color data and the resultant image data (printing information) is output.

35 In step S903 of Figure 11, if at least of one of flags including the ink cartridge flag, no-ink flag, and remaining ink flag associated with the designated alternative color is 1, the designated color is not available. In this case, a message 6 is displayed in step S904.

30 The message 6 is displayed in a status window on the display screen as shown in Figure 24. The status window, as shown in Figure 24, contains a message telling that the color designated as the alternative color is not available and also contains "execute" and "stop" buttons. Either button may be selected via input means such as a mouse or a keyboard of the host computer, so that the selected operation will be executed.

40 In the case where the stop button is selected, it is determined in step S905 of Figure 11 that a forced aborting command has been issued, and thus the program goes to step S802 of Figure 9. If the "execute" button is selected, the program returns to step S901 of Figure 11 in which the message 5 is displayed again. Alternatively, in the case where the "stop" button is selected in the window of Figure 24, the program may return to step S807 of Figure 9 so that the message shown in Figure 21 will be displayed again in the status window.

45 Once the alternative color has been selected, detection of the ink cartridge flag, no-ink flag, and remaining ink flag is performed only for those associated with the designated alternative color, during the following process steps until outputting of all image data (printing information) is completed.

50 The above-described process of checking the flags in steps S505 and S506 of Figure 5 and step S801 of Figure 9 and the succeeding process according to the result of the checking are performed repeatedly until it is concluded in step S804 of Figure 9 that all image data (printing information) has been output. In the alternative color mode, the checking of the ink cartridge flag in step S505 of Figure 5, the no-ink flag in step S506 of Figure 5, and the remaining ink flag in step S801 of Figure 9, and is performed only for those associated with the designated alternative color during the above-described repetition of process steps until all image data (printing information) has been output.

55 If it is concluded in step S804 that all image data (printing information) has been output, the program goes to step S805. If an "end" command is not issued in step S805, then the program returns to step S502 of Figure 5 and waits for another command telling that generation of printing information should be started.

On the other hand, if it is concluded in step S504 of Figure 5 that the current color mode is in the color printing mode, then the program goes to step S601 of Figure 6. In step S601, the program checks all the ink cartridge flags associated with individual colors. If the ink cartridge flag is 0, that is, all ink cartridges are mounted on the printer, then the program goes to step S602. In step S602, the program checks all the no-ink flags associated with individual colors. If all the no-ink flags are 0, that is, there is ink in all ink cartridges, then the program goes to step S812 of Figure 9. In

step S812, the program checks all the remaining ink flags associated with individual colors. If all the remaining ink flags are 0, that is, the remaining amounts of ink are enough, then the program goes to step S813. In step S813, printing information is generated by converting image data into a form suitable for printing. Then in step S814 the generated image data (printing information) is output to the printer.

5 If it is concluded in step S601 of Figure 6 that a particular ink cartridge flag is 1, that is, an ink cartridge of a particular color is not mounted on the printer, then the program goes to step S603 and the generation of printing information is temporarily stopped. Then in step S604, a message 1 is displayed. As in the case of Embodiment 1 described above, the message 1 is also displayed in a status window on the display screen as shown in Figure 17. As shown in Figure 17, the status window contains a message telling that a particular ink cartridge is not mounted on the printer and also 10 telling the color of that cartridge. The status window also contains "execute" and "stop" buttons. Either button may be selected via input means such as a mouse or a keyboard of the host computer, so that the selected operation will be executed. After mounting an ink cartridge according to the message shown in Figure 17, if the "execute" button is selected, it is determined in step S605 of Figure 6 that replacement of an ink cartridge has been performed, and thus 15 the program goes to step S301 of Figure 3. In the case where the stop button is selected in the status window of Figure 17, ink cartridge replacement is not performed in step S605 of Figure 6, and it is determined in step S606 that a forced aborting command has been issued, and thus the generation of printing information is canceled and the program returns to step S502 in which the program waits until a command telling that generation of printing information should be started is issued again.

20 In the case where the program has branched to step S301, a message 4 is displayed. As in the case of Embodiment 1 described above, the message 4 is also displayed in a status window on the display screen as shown in Figure 22. As shown in Figure 22, the status window contains a message telling that the printer will start cleaning the print head, and also contains "execute" and "stop" buttons. Either button may be selected via input means such as a mouse or a keyboard of the host computer, so that the selected operation will be executed. In the case where the stop button is selected, it is determined in step S302 of Figure 3 that a forced aborting command has been issued, and thus 25 the generation of printing information is canceled and the program returns to step S502 of Figure 5 and waits until a command telling that generation of printing information should be started is issued again. Alternatively, in the case where it has been concluded in the above step S302 of Figure 3 that a forced aborting command has been issued, the program may return to step S604 of Figure 6 so that the message shown in Figure 17 will be displayed again in the status window. If the "execute" button is selected in the status window of Figure 22, it is concluded in step S303 of Figure 3 that an 30 "execute" command has been issued, and thus in step S304 a cleaning execution command is sent to the printer. On reception of the cleaning execution command, the printer sets the cleaning execution flag to 1 and starts the cleaning operation. When the cleaning operation is completed, the printer immediately resets the cleaning execution flag to 0. In step S305, if a cleaning completion signal indicating that the cleaning execution flag = 0 is received, the no-ink flag corresponding to the color of the cleaned ink cartridge is reset. Then in step S307, the generation of printing information is started again, and the program goes to step S602 of Figure 6. Alternatively, in the above step S306 of Figure 3, the 35 flag may be reset by the printer itself instead of the host computer.

40 On the other hand, if it is concluded in step S602 of Figure 6 that the no-ink flag associated with a particular color is 1, that is, there is no ink in a particular ink cartridge, then the program goes to step S607 at which the generation of printing information is temporarily stopped. Then in step S608, a message 2 is displayed. As in the case of Embodiment 1 described above, the message 2 is also displayed in a status window on the display screen as shown in Figure 18. As shown in Figure 18, the status window contains a message telling that a particular ink cartridge has no ink in it and also telling the ink color of that cartridge. The status window also contains "execute" and "stop" buttons. Either button may be selected via input means such as a mouse or a keyboard of the host computer, so that the selected operation will be executed. After replacing the corresponding ink cartridge by a new one according to the message shown in Figure 45 18, if the "execute" button is selected, it is determined in step S609 that replacement of the ink cartridge has been performed, and thus the program goes to step S301 shown in Figure 3. In the case where the stop button is selected in the status window of Figure 18, ink cartridge replacement is not performed in step S606, and it is determined in step S610 that a forced aborting command has been issued, and thus the generation of printing information is canceled and the program returns to step S502 of Figure 5 in which the program waits until a command telling that generation of printing information should be started is issued again.

50 In the case where the program has branched to step S301, a message 4 is displayed. As in the case of Embodiment 1 described above, the message 4 is also displayed in a status window on the display screen as shown in Figure 22. As shown in Figure 22, the status window contains a message telling that the printer will start cleaning the print head, and also contains "execute" and "stop" buttons. Either button may be selected via input means such as a mouse or a 55 keyboard of the host computer, so that the selected operation will be executed. In the case where the stop button is selected, it is determined in step S302 of Figure 3 that a forced aborting command has been issued, and thus the generation of printing information is canceled and the program returns to step S502 of Figure 5 and waits until a command telling that generation of printing information should be started is issued again. Alternatively, in the case where it has been concluded in the above step S302 of Figure 3 that a forced aborting command has been issued, the program may

return to step S608 of Figure 6 so that the message shown in Figure 18 will be displayed again in the status window. If the "execute" button is selected in the status window of Figure 22, it is concluded in step S303 of Figure 3 that an "execute" command has been issued, and thus in step S304 a cleaning execution command is sent to the printer. On reception of the cleaning execution command, the printer sets the cleaning execution flag to 1 and starts the cleaning operation. When the cleaning operation is completed, the printer immediately resets the cleaning execution flag to 0. In step S305, if a cleaning completion signal indicating that the cleaning execution flag = 0 is received, the no-ink flag corresponding to the color of the cleaned ink cartridge is reset. Then in step S307, the generation of printing information is started again, and the program goes to step S711 of Figure 8. Alternatively, in the above step S306 of Figure 3, the flag may be reset by the printer itself instead of the host computer.

10 In step S812 of Figure 10, if it is concluded that a particular remaining ink flag is 1, that is, the remaining amount of ink in a particular color ink cartridge is not enough, then the program goes to step S817 at which the generation of printing information is temporarily stopped. Then in step S818, a message 3 is displayed. As in the case of Embodiment 1 described above, the message 3 is also displayed in a status window on the display screen as shown in Figure 19. The status window, as shown in Figure 19, contains a message telling that the remaining amount of ink is not enough and thus printing will be stopped before completion if the amount of data to be printed is too large, and also telling the color of that ink. The status window also contains "execute" and "stop" buttons. Either button may be selected via input means such as a mouse or a keyboard of the host computer, so that the selected operation will be executed. After replacing the corresponding ink cartridge by a new one according to the message shown in Figure 19, if the execution button is selected, it is determined in step S819 of Figure 10 that replacement of the ink cartridge is complete, and the program then goes to step S301 shown in Figure 3. In the case where the stop button is selected in the status window of Figure 19, no ink cartridge is replaced in step S819 of Figure 10, and it is determined in step S820 that an "abort" command has been issued, and the program goes to step S821 to start generation of printing information again. The program then goes to step S813. Even in the case where only a small amount of ink remains, printing may be performed on a few further pages if the image to be printed has a low dot density as in the case of a usual document, almost all 20 portions of which are in the form of characters. Therefore, the generation of printing information is not forced to be canceled in this case and the user can select whether the ink cartridge is immediately replaced with a new one or printing is performed without replacement of the ink cartridge.

25 In the case where the program has branched to step S301, a message 4 is displayed. As in the case of Embodiment 1 described above, the message 4 is also displayed in a status window on the display screen as shown in Figure 22. As shown in Figure 22, the status window contains a message telling that the printer will start cleaning the print head, and also contains "execute" and "stop" buttons. Either button may be selected via input means such as a mouse or a keyboard of the host computer, so that the selected operation will be executed. In the case where the stop button is selected, it is determined in step S302 of Figure 3 that a forced aborting command has been issued, and thus the generation of printing information is canceled and the program returns to step S502 of Figure 5 and waits until a command 30 telling that generation of printing information should be started is issued again. Alternatively, in the case where it has been concluded in the above step S302 of Figure 3 that a forced aborting command has been issued, the program may return to step S808 of Figure 9 so that the message shown in Figure 19 will be displayed again in the status window. If the "execute" button is selected in the status window of Figure 22, it is concluded in step S303 of Figure 3 that an "execute" command has been issued, and thus in step S304 a cleaning execution command is sent to the printer. On 35 reception of the cleaning execution command, the printer sets the cleaning execution flag to 1 and starts the cleaning operation. When the cleaning operation is completed, the printer immediately resets the cleaning execution flag to 0. In step S305, if a cleaning completion signal indicating that the cleaning execution flag = 0 is received, the remaining ink flag corresponding to the color of the cleaned ink cartridge is reset. Then in step S307, the generation of printing information is started again, and the program goes to step S813 of Figure 10. Alternatively, in the above step S306 of Figure 40 45 3, the flag may be reset by the printer itself instead of the host computer.

45 The above-described process of checking the flags in steps S601 and S602 of Figure 6 and step S812 of Figure 10 and the succeeding process according to the result of the checking are performed repeatedly until it is concluded in step S815 of Figure 10 that all image data (printing information) has been output. If it is concluded in step S815 that all image data (printing information) has been output, the program goes to step S816. If an "end" command is not issued 50 in step S816, then the program returns to step S502 of Figure 5 and waits for another command telling that generation of printing information should be started.

55 As in the previous embodiments, the host computer can know the printer status regarding the presence of ink cartridges, the lack of ink, and the amount of remaining ink. This feature of the present embodiment also provides a great advantage particularly when the printer is installed at a location rather far from the host computer or when the printer is shared by a plurality of computers via a network.

Furthermore in the present embodiment, the detection of the ink cartridge flags, no-ink flags, and remaining ink flags is performed depending on the designated color mode, and thus the detection time is reduced when operating in the monochrome printing mode in which only black ink is used, which results in an improvement in the printing speed. This also prevents the printing operation from being unnecessarily stopped by status information regarding an ink color

which is not used. Furthermore, in this embodiment it is not required to determine which color should be used in printing, and therefore the processing load associated with handling of image data is reduced. In this embodiment, even if the remaining amount of black ink becomes very small during a printing operation in the monochrome printing mode, it is possible to continue the printing operation by designating an alternative color without replacing the ink cartridge with a new one. This provides an advantage particularly when the printing operation has to be completed without a delay.

5

## EMBODIMENT 5

Referring to the flowcharts shown in Figures 3, 12 and 13, the process of a fifth embodiment according to the present invention will be described below.

In step S1001 shown in Figure 12, the program begins with receiving status information from the printer. In step S1002, if a command is received which indicates that generation of printing information should be started, the program goes to step S1003. In step S1003 the program checks ink cartridge flags. If the ink cartridge flags are 0, that is, all ink cartridges are mounted on the printer, then the program goes to step S1004. In step S1004, the program checks no-ink flags. If all the no-ink flags are 0, that is, there is ink in all ink cartridges, then the program goes to step S1101 of Figure 13. In step S1101, the program checks remaining ink flags. If the remaining ink flags are 0, that is, the remaining amount of ink is enough, then the program goes to step S1105. In step S1105, printing information is generated by converting image data into a form suitable for printing. Then in step S1106 the generated image data (printing information) is output to the printer.

If it is concluded in step S1003 of Figure 12 that a particular ink cartridge flag is 1, that is, a particular ink cartridge is not mounted on the printer, then the program goes to step S1005 and the generation of printing information is temporarily stopped. Then in step S1006, a message 1 is displayed. As in the case of Embodiment 1 described above, the message 1 is also displayed in a status window on the display screen as shown in Figure 17. As shown in Figure 17, the status window contains a message telling that a particular ink cartridge is not mounted on the printer and also telling the color of that cartridge. The status window also contains "execute" and "stop" buttons. Either button may be selected via input means such as a mouse or a keyboard of the host computer, so that the selected operation will be executed. After mounting an ink cartridge according to the message shown in Figure 17, if the execution button is selected, it is determined in step S1007 shown in Figure 12 that replacement of an ink cartridge has been performed, and the program then goes to step S301 shown in Figure 3. In the case where the stop button is selected in the status window of Figure 17, ink cartridge replacement in step S1007 of Figure 12 is not performed, and it is determined in step S1008 that a forced aborting command has been issued, and thus the generation of printing information is canceled and the program returns to step S1002 at which the program waits until a command telling that generation of printing information should be started is issued again.

In the case where the program has branched to step S301, a message 4 is displayed. As in the case of Embodiment 1 described above, the message 4 is also displayed in a status window on the display screen as shown in Figure 22. As shown in Figure 22, the status window contains a message telling that the printer will start cleaning the print head, and also contains "execute" and "stop" buttons. Either button may be selected via input means such as a mouse or a keyboard of the host computer, so that the selected operation will be executed. In the case where the stop button is selected, it is determined in step S302 of Figure 3 that a forced aborting command has been issued, and thus the generation of printing information is canceled and the program returns to step S1002 of Figure 12 and waits until a command telling that generation of printing information should be started is issued again. Alternatively, in the case where it has been concluded in the above step S302 of Figure 3 that a forced aborting command has been issued, the program may return to step S1006 of Figure 12 so that the message shown in Figure 17 will be displayed again in the status window. If the "execute" button is selected in the status window of Figure 22, it is concluded in step S303 of Figure 3 that an "execute" command has been issued, and thus in step S304 a cleaning execution command is sent to the printer. On reception of the cleaning execution command, the printer sets the cleaning execution flag to 1 and starts the cleaning operation. When the cleaning operation is completed, the printer immediately resets the cleaning execution flag to 0. In step S305, if a cleaning completion signal indicating that the cleaning execution flag = 0 is received, the no-ink flag corresponding to the color of the cleaned ink cartridge is reset. Then in step S307 of Figure 3, the generation of printing information is started again, and the program goes to step S1004 of Figure 12. Alternatively, in the above step S306 of Figure 3, the flag may be reset by the printer itself instead of the host computer.

On the other hand, if it is concluded in step S1004 of Figure 12 that the no-ink flag is 1 which indicates that there is no ink in an ink cartridge, then the program goes to step S1009 at which the generation of printing information is temporarily stopped. Then in step S1010, a message 2 is displayed. As in the case of Embodiment 1 described above, the message 2 is also displayed in a status window on the display screen as shown in Figure 18. As shown in Figure 18, the status window contains a message telling that a particular ink cartridge has no ink in it and also telling the ink color of that cartridge. The status window also contains "execute" and "stop" buttons. Either button may be selected via input means such as a mouse or a keyboard of the host computer, so that the selected operation will be executed. After replacing the corresponding ink cartridge with a new one according to the message shown in Figure 18, if the execution

button is selected, it is determined in step S1011 of Figure 12 that replacement of the ink cartridge has been performed, and the program then goes to step S301 shown in Figure 3. In the case where the stop button is selected in the status window of Figure 18, no ink cartridge is replaced in step S1011 of Figure 12, and it is determined in step S1012 that a forced aborting command has been issued, and thus the generation of printing information is canceled and the program returns to step S1002 and waits until a command telling that generation of printing information should be started is issued again.

In the case where the program has branched to step S301, a message 4 is displayed. As in the case of Embodiment 1 described above, the message 4 is also displayed in a status window on the display screen as shown in Figure 22. As shown in Figure 22, the status window contains a message telling that the printer will start cleaning the print head, and also contains "execute" and "stop" buttons. Either button may be selected via input means such as a mouse or a keyboard of the host computer, so that the selected operation will be executed. In the case where the stop button is selected, it is determined in step S302 of Figure 3 that a forced aborting command has been issued, and thus the generation of printing information is canceled and the program returns to step S1002 of Figure 12 and waits until a command telling that generation of printing information should be started is issued again. Alternatively, in the case where it has been concluded in the above step S302 of Figure 3 that a forced aborting command has been issued, the program may return to step S1010 of Figure 12 so that the message shown in Figure 18 will be displayed again in the status window. If the "execute" button is selected in the status window of Figure 22, it is concluded in step S303 of Figure 3 that an "execute" command has been issued, and thus in step S304 a cleaning execution command is sent to the printer. On reception of the cleaning execution command, the printer sets the cleaning execution flag to 1 and starts the cleaning operation. When the cleaning operation is completed, the printer immediately resets the cleaning execution flag to 0. In step S305, if a cleaning completion signal indicating that the cleaning execution flag = 0 is received, the no-ink flag corresponding to the color of the cleaned ink cartridge is reset. Then in step S307, the generation of printing information is started again, and the program goes to step S1101 of Figure 13. Alternatively, in the above step S306 of Figure 3, the flag may be reset by the printer itself instead of the host computer.

In step S1101 of Figure 11, if it is concluded that a particular remaining ink flag is 1, that is, the remaining amount of ink in a particular color ink cartridge is not enough, then the program goes to step S1102 to read the value of "Count" representing the number of dots that can be printed further. The maximum possible number of dots that can be printed after the remaining ink flag in the printer becomes 1 is estimated, and this estimated value is used as the initial value of "Count". This value is previously set in a counter disposed in the printer. The printer counts the number of dots that are printed after the remaining ink flag became 1, and the value of "Count" is decremented on the basis of the above counted value. The program then goes to step S1103 and determines the number (D) of dots to be printed. Then comparison is made in step S1104. If  $D \leq Count$ , the program goes to step S1105 to continue the processing of the image data (printing information).

On the other hand, if  $D > Count$ , the amount of remaining ink is insufficient to print all the printing data which should be printed. In this case, the program goes to step S1109 at which the generation of printing information is temporarily stopped. Then in step S1110, a message 3' is displayed. The message 3' is displayed in a status window on the display screen as shown in Figure 20. The status window, as shown in Figure 20, contains a message telling that the remaining amount of ink is not enough and thus printing will be stopped before completion and also telling the color of that ink. The status window also contains "execute" and "stop" buttons. Either button may be selected via input means such as a mouse or a keyboard of the host computer, so that the selected operation will be executed. After replacing the corresponding ink cartridge with a new one according to the message shown in Figure 20, if the execution button is selected, it is determined in step S1111 of Figure 13 that replacement of the ink cartridge is complete, and the program then goes to step S301 shown in Figure 3. In the case where the stop button is selected in the status window of Figure 20, no ink cartridge is replaced in step S1111 of Figure 13, and it is determined in step S1112 that a "neglect" command has been issued, and the program goes to step S1113 to start generation of printing information again. The program then goes to step S1105. In this case, the generation of printing information is not canceled.

In the case where the program has branched to step S301, a message 4 is displayed. As in the case of Embodiment 1 described above, the message 4 is also displayed in a status window on the display screen as shown in Figure 22. As shown in Figure 22, the status window contains a message telling that the printer will start cleaning the print head, and also contains "execute" and "stop" buttons. Either button may be selected via input means such as a mouse or a keyboard of the host computer, so that the selected operation will be executed. In the case where the stop button is selected, it is determined in step S302 of Figure 3 that a forced aborting command has been issued, and thus the generation of printing information is canceled and the program returns to step S1002 of Figure 12 and waits until a command telling that generation of printing information should be started is issued again. Alternatively, in the case where it has been concluded in the above step S302 of Figure 3 that a forced aborting command has been issued, the program may return to step S1110 of Figure 13 so that the message shown in Figure 20 will be displayed again in the status window. If the "execute" button is selected in the status window of Figure 22, it is concluded in step S303 of Figure 3 that an "execute" command has been issued, and thus in step S304 a cleaning execution command is sent to the printer. On reception of the cleaning execution command, the printer sets the cleaning execution flag to 1 and starts the cleaning

operation. When the cleaning operation is completed, the printer immediately resets the cleaning execution flag to 0. In step S305, if a cleaning completion signal indicating that the cleaning execution flag = 0 is received, the remaining ink flag corresponding to the color of the cleaned ink cartridge is reset. Then in step S307, the generation of printing information is started again, and the program goes to step S1105 of Figure 13. Alternatively, in the above step S306 of Figure 5 3, the flag may be reset by the printer itself instead of the host computer.

The above-described process of checking the flags in steps S1003 and S1004 of Figure 12 and step S1101 of Figure 13 and the succeeding process according to the result of the checking are performed repeatedly until it is concluded in step S1107 of Figure 13 that all image data (printing information) has been output. If it is concluded in step 10 S1107 that all image data (printing information) has been output, the program goes to step S1108. If an "end" command is not issued in step S1108, then the program returns to step S1002 of Figure 12 and waits for another command telling 15 that generation of printing information should be started.

As in the previous embodiments described above, the host computer can know the printer status regarding the presence of ink cartridges, the lack of ink, and the amount of remaining ink. This feature of the present embodiment also provides a great advantage particularly when the printer is installed at a location rather far from the host computer 15 or when the printer is shared by a plurality of computers via a network.

Furthermore, in this embodiment, when the remaining amount of ink becomes small, it is determined whether all data can be printed on the basis of the comparison between the number of dots to be printed and the estimated maximum possible number of dots thereby providing high reliability in printing operations.

## 20 EMBODIMENT 6

Referring to the flowcharts shown in Figures 3, 12 and 14, the process of another embodiment according to the present invention will be described below.

In step S1001 shown in Figure 12, the program begins with receiving status information from the printer. In step 25 S1002, if a command is received which indicates that generation of printing information should be started, the program goes to step S1003. In step S1003 the program checks ink cartridge flags. If the ink cartridge flag is 0, that is, all ink cartridges are mounted on the printer, then the program goes to step S1004. In step S1004, the program checks no-ink flags. If all the no-ink flags are 0, that is, there is ink in all ink cartridges, then the program goes to step S1201 of Figure 30 14. In step S1201, the program checks a remaining ink flag. If the remaining ink flag is 0, that is, the remaining amount of ink is enough, then the program goes to step S1205. In step S1205, printing information is generated by converting image information into a form suitable for printing. Then in step S1206 the generated printing information is output to the printer band by band.

If it is concluded in step S1003 of Figure 12 that a particular ink cartridge flag is 1, that is, a particular ink cartridge 35 is not mounted on the printer, then the program goes to step S1005 and the generation of printing information is temporarily stopped. Then in step S1006, a message 1 is displayed. As in the case of Embodiment 1 described above, the message 1 is also displayed in a status window on the display screen as shown in Figure 17. As shown in Figure 17, the status window contains a message telling that a particular ink cartridge is not mounted on the printer and also telling the color of that cartridge. The status window also contains "execute" and "stop" buttons. Either button may be selected via input means such as a mouse or a keyboard of the host computer, so that the selected operation will be executed. 40 After mounting an ink cartridge according to the message shown in Figure 17, if the execution button is selected, it is determined in step S1007 shown in Figure 12 that replacement of an ink cartridge has been performed, and the program then goes to step S301 shown in Figure 3. In the case where the stop button is selected in the status window of Figure 17, ink cartridge replacement in step S1007 of Figure 12 is not performed, and it is determined in step S1008 that a forced aborting command has been issued, and thus the generation of printing information is canceled and the program 45 returns to step S1002 at which the program waits until a command telling that generation of printing information should be started is issued again.

In the case where the program has branched to step S301, a message 4 is displayed. As in the case of Embodiment 1 described above, the message 4 is also displayed in a status window on the display screen as shown in Figure 22. As shown in Figure 22, the status window contains a message telling that the printer will start cleaning the print head, 50 and also contains "execute" and "stop" buttons. Either button may be selected via input means such as a mouse or a keyboard of the host computer, so that the selected operation will be executed. In the case where the stop button is selected, it is determined in step S302 of Figure 3 that a forced aborting command has been issued, and thus the generation of printing information is canceled and the program returns to step S1002 of Figure 12 and waits until a command telling that generation of printing information should be started is issued again. Alternatively, in the case where 55 it has been concluded in the above step S302 of Figure 3 that a forced aborting command has been issued, the program may return to step S1006 of Figure 12 so that the message shown in Figure 17 will be displayed again in the status window. If the "execute" button is selected in the status window of Figure 22, it is concluded in step S303 of Figure 3 that an "execute" command has been issued, and thus in step S304 a cleaning execution command is sent to the printer. On reception of the cleaning execution command, the printer sets the cleaning execution flag to 1 and starts the cleaning

operation. When the cleaning operation is completed, the printer immediately resets the cleaning execution flag to 0. In step S305, if a cleaning completion signal indicating that the cleaning execution flag = 0 is received, the no-ink flag corresponding to the color of the cleaned ink cartridge is reset. Then in step S307 of Figure 3, the generation of printing information is started again, and the program goes to step S1004 of Figure 12. Alternatively, in the above step S306 of Figure 3, the flag may be reset by the printer itself instead of the host computer.

On the other hand, if it is concluded in step S1004 of Figure 12 that the no-ink flag is 1 which indicates that there is no ink in an ink cartridge, then the program goes to step S1009 at which the generation of printing information is temporarily stopped. Then in step S1010, a message 2 is displayed. As in the case of Embodiment 1 described above, the message 2 is also displayed in a status window on the display screen as shown in Figure 18. As shown in Figure 18, the status window contains a message telling that a particular ink cartridge has no ink in it and also telling the ink color of that cartridge. The status window also contains "execute" and "stop" buttons. Either button may be selected via input means such as a mouse or a keyboard of the host computer, so that the selected operation will be executed. After replacing the corresponding ink cartridge with a new one according to the message shown in Figure 18, if the execution button is selected, it is determined in step S1011 of Figure 12 that replacement of the ink cartridge has been performed, and the program then goes to step S301 shown in Figure 3. In the case where the stop button is selected in the status window of Figure 18, no ink cartridge is replaced in step S1011 of Figure 12, and it is determined in step S1012 that a forced aborting command has been issued, and thus the generation of printing information is canceled and the program returns to step S1002 and waits until a command telling that generation of printing information should be started is issued again.

In the case where the program has branched to step S301, a message 4 is displayed. As in the case of Embodiment 1 described above, the message 4 is also displayed in a status window on the display screen as shown in Figure 22. As shown in Figure 22, the status window contains a message telling that the printer will start cleaning the print head, and also contains "execute" and "stop" buttons. Either button may be selected via input means such as a mouse or a keyboard of the host computer, so that the selected operation will be executed. In the case where the stop button is selected, it is determined in step S302 of Figure 3 that a forced aborting command has been issued, and thus the generation of printing information is canceled and the program returns to step S1002 of Figure 12 and waits until a command telling that generation of printing information should be started is issued again. Alternatively, in the case where it has been concluded in the above step S302 of Figure 3 that a forced aborting command has been issued, the program may return to step S1010 of Figure 12 so that the message shown in Figure 18 will be displayed again in the status window. If the "execute" button is selected in the status window of Figure 22, it is concluded in step S303 of Figure 3 that an "execute" command has been issued, and thus in step S304 a cleaning execution command is sent to the printer. On reception of the cleaning execution command, the printer sets the cleaning execution flag to 1 and starts the cleaning operation. When the cleaning operation is completed, the printer immediately resets the cleaning execution flag to 0. In step S305, if a cleaning completion signal indicating that the cleaning execution flag = 0 is received, the no-ink flag corresponding to the color of the cleaned ink cartridge is reset. Then in step S307, the generation of printing information is started again, and the program goes to step S1201 of Figure 14. Alternatively, in the above step S306 of Figure 3, the flag may be reset by the printer itself instead of the host computer.

In step S1201 of Figure 14, if it is concluded that a particular remaining ink flag is 1, that is, the remaining amount of ink in a particular color ink cartridge is not enough, then the program goes to step S1202 to read the value of "Count" representing the number of dots that can be printed further. The maximum possible number of dots that can be printed after the remaining ink flag in the printer becomes 1 is estimated, and this estimated value is used as the initial value of "Count". This value is previously set in a counter disposed in the printer. The program then goes to step S1203 and determines the number (D) of dots to be printed. Then in step S1204, comparison is made. If  $D \leq Count$ , the program goes to step S1205 to continue the processing of the image data (printing information).

On the other hand, if  $D > Count$ , the amount of remaining ink is insufficient to print all the printing data which should be printed. In this case, the program goes to step S1210 at which the generation of printing information is temporarily stopped. Then in step S1211, a message 3 is displayed. The message 3 is displayed in a status window on the display screen as shown in Figure 20. The status window, as shown in Figure 20, contains a message telling that the remaining amount of ink is not enough and thus printing will be stopped before completion and also telling the color of that ink. The status window also contains "execute" and "stop" buttons. Either button may be selected via input means such as a mouse or a keyboard of the host computer, so that the selected operation will be executed. After replacing the corresponding ink cartridge with a new one according to the message shown in Figure 20, if the execution button is selected, it is determined in step S1212 of Figure 14 that replacement of the ink cartridge is complete, and the program then goes to step S301 shown in Figure 3. In the case where the stop button is selected in the status window of Figure 20, no ink cartridge is replaced in step S1212 of Figure 14, and it is determined in step S1213 that an "abort" command has been issued, and the program goes to step S1214 to start generation of printing information again. The program then goes to step S1205. In this case, the generation of printing information is not canceled.

In the case where the program has branched to step S301, a message 4 is displayed. As in the case of Embodiment 1 described above, the message 4 is also displayed in a status window on the display screen as shown in Figure 22.

As shown in Figure 22, the status window contains a message telling that the printer will start cleaning the print head, and also contains "execute" and "stop" buttons. Either button may be selected via input means such as a mouse or a keyboard of the host computer, so that the selected operation will be executed. In the case where the stop button is selected, it is determined in step S302 of Figure 3 that a forced aborting command has been issued, and thus the generation of printing information is canceled and the program returns to step S1002 of Figure 12 and waits until a command telling that generation of printing information should be started is issued again. Alternatively, in the case where it has been concluded in the above step S302 of Figure 3 that a forced aborting command has been issued, the program may return to step S1210 of Figure 14 so that the message shown in Figure 20 will be displayed again in the status window. If the "execute" button is selected in the status window of Figure 22, it is concluded in step S303 of Figure 3 that an "execute" command has been issued, and thus in step S304 a cleaning execution command is sent to the printer. On reception of the cleaning execution command, the printer sets the cleaning execution flag to 1 and starts the cleaning operation. When the cleaning operation is completed, the printer immediately resets the cleaning execution flag to 0. In step S305, if a cleaning completion signal indicating that the cleaning execution flag = 0 is received, the remaining ink flag corresponding to the color of the cleaned ink cartridge is reset. Then in step S307, the generation of printing information is started again, and the program goes to step S1205 of Figure 14. Alternatively, in the above step S306 of Figure 3, the flag may be reset by the printer itself instead of the host computer.

The above-described process of checking the flags in steps S1003 and S1004 of Figure 12 and step S1201 of Figure 14 and the succeeding process according to the result of the checking are performed repeatedly until it is concluded in step S1207 of Figure 14 that all image data (printing information) has been output. If it is concluded in step S1207 that all image data (printing information) has been output, the program goes to step S1208 to update the status regarding the number of dots that can be printed further. The program then goes to step S1209. If an "end" command is not issued in step S1209, then the program returns to step S1002 of Figure 12 and waits for another command telling that generation of printing information should be started.

As in the previous embodiments described above, the host computer can know the printer status regarding the presence of ink cartridges, the lack of ink, and the amount of remaining ink. This feature of the present embodiment also provides a great advantage particularly when the printer is installed at a location rather far from the host computer or when the printer is shared by a plurality of computers via a network.

Furthermore, as in the previous embodiment described above, when the remaining amount of ink becomes small, it is determined whether all data can be printed on the basis of the comparison between the number of dots to be printed and the estimated maximum possible number of dots thereby providing high reliability in printing operations. Furthermore, in this embodiment, when a printing operation is completed, the host computer determines the number of dots that can be printed further on the basis of the number of dots that were printed in that latest printing operation, and the resultant value is stored in the printer as a new status value. Therefore, this technique is applicable to a printer having no capability of counting the number of dots that have been printed already.

## EMBODIMENT 7

Referring to the flowcharts shown in Figures 3, 15 and 16, the process of another embodiment according to the present invention will be described below.

In the beginning of the program, the remaining ink flag is reset in step S1301 of Figure 15. Then in step S1302, the program starts receiving status information from the printer. In step S1303, if a command is received which indicates that generation of printing information should be started, the program goes to step S1304. In step S1304 the program checks ink cartridge flags. If the ink cartridge flag is 0, that is, all ink cartridges are mounted on the printer, then the program goes to step S1305. In step S1305, the program checks no-ink flags. If all the no-ink flags are 0, that is, there is ink in all ink cartridges, then the program goes to step S1401 of Figure 16. In step S1401, the program checks remaining ink flags. If the remaining ink flags are 0, that is, the remaining amounts of ink are enough, then the program goes to step S1402. In step S1402, printing information is generated by converting image information into a form suitable for printing. Then in step S1203 the generated printing information is output to the printer band by band.

If it is concluded in step S1304 of Figure 15 that a particular ink cartridge flag is 1, that is, a particular ink cartridge is not mounted on the printer, then the program goes to step S1306 and the generation of printing information is temporarily stopped. Then in step S1307, a message 1 is displayed. As in the case of Embodiment 1 described above, the message 1 is also displayed in a status window on the display screen as shown in Figure 17. As shown in Figure 17, the status window contains a message telling that a particular ink cartridge is not mounted on the printer and also telling the color of that cartridge. The status window also contains "execute" and "stop" buttons. Either button may be selected via input means such as a mouse or a keyboard of the host computer, so that the selected operation will be executed. After mounting an ink cartridge according to the message shown in Figure 17, if the execution button is selected, it is determined in step S1308 shown in Figure 15 that replacement of an ink cartridge has been performed, and the program then goes to step S301 shown in Figure 3. In the case where the stop button is selected in the status window of Figure 17, no ink cartridge is replaced in step S1308 of Figure 15, and it is determined in step S1309 that a forced aborting

command has been issued, and thus the generation of printing information is canceled and the program returns to step S1303 and waits until a command telling that generation of printing information should be started is issued again.

In the case where the program has branched to step S301, a message 4 is displayed. As in the case of Embodiment 1 described above, the message 4 is also displayed in a status window on the display screen as shown in Figure 22. As shown in Figure 22, the status window contains a message telling that the printer will start cleaning the print head, and also contains "execute" and "stop" buttons. Either button may be selected via input means such as a mouse or a keyboard of the host computer, so that the selected operation will be executed. In the case where the stop button is selected, it is determined in step S302 of Figure 3 that a forced aborting command has been issued, and thus the generation of printing information is canceled and the program returns to step S1303 of Figure 15 and waits until a command telling that generation of printing information should be started is issued again. Alternatively, in the case where it has been concluded in the above step S302 of Figure 3 that a forced aborting command has been issued, the program may return to step S1307 of Figure 15 so that the message shown in Figure 17 will be displayed again in the status window. If the "execute" button is selected in the status window of Figure 22, it is concluded in step S303 of Figure 3 that an "execute" command has been issued, and thus in step S304 a cleaning execution command is sent to the printer. On reception of the cleaning execution command, the printer sets the cleaning execution flag to 1 and starts the cleaning operation. When the cleaning operation is completed, the printer immediately resets the cleaning execution flag to 0. In step S305, if a cleaning completion signal indicating that the cleaning execution flag = 0 is received, the no-ink flag corresponding to the color of the cleaned ink cartridge is reset. Then in step S307 of Figure 3, the generation of printing information is started again, and the program goes to step S1305 of Figure 15. Alternatively, in the above step S306 of Figure 3, the flag may be reset by the printer itself instead of the host computer.

On the other hand, if it is concluded in step S1305 of Figure 15 that a particular no-ink flag is 1, that is, there is no ink in a particular ink cartridge, then the program goes to step S1310 at which the generation of printing information is temporarily stopped. Then in step S1311, a message 2 is displayed. As in the case of Embodiment 1 described above, the message 2 is also displayed in a status window on the display screen as shown in Figure 18. As shown in Figure 18, the status window contains a message telling that a particular ink cartridge has no ink in it and also telling the ink color of that cartridge. The status window also contains "execute" and "stop" buttons. Either button may be selected via input means such as a mouse or a keyboard of the host computer, so that the selected operation will be executed. After replacing the corresponding ink cartridge by a new one according to the message shown in Figure 18, if the execution button is selected, it is determined in step S1312 of Figure 15 that replacement of the ink cartridge has been performed, and the program then goes to step S301 shown in Figure 3. In the case where the stop button is selected in the status window of Figure 18, no ink cartridge is replaced in step S1312 of Figure 15, and it is determined in step S1313 that a forced aborting command has been issued, and thus the generation of printing information is canceled and the program returns to step S1303 and waits until a command telling that generation of printing information should be started is issued again.

In the case where the program has branched to step S301, a message 4 is displayed. As in the case of Embodiment 1 described above, the message 4 is also displayed in a status window on the display screen as shown in Figure 22. As shown in Figure 22, the status window contains a message telling that the printer will start cleaning the print head, and also contains "execute" and "stop" buttons. Either button may be selected via input means such as a mouse or a keyboard of the host computer, so that the selected operation will be executed. In the case where the stop button is selected, it is determined in step S302 of Figure 3 that a forced aborting command has been issued, and thus the generation of printing information is canceled and the program returns to step S1303 of Figure 15 and waits until a command telling that generation of printing information should be started is issued again. Alternatively, in the case where it has been concluded in the above step S302 of Figure 3 that a forced aborting command has been issued, the program may return to step S1311 of Figure 15 so that the message shown in Figure 18 will be displayed again in the status window. If the "execute" button is selected in the status window of Figure 22, it is concluded in step S303 of Figure 3 that an "execute" command has been issued, and thus in step S304 a cleaning execution command is sent to the printer. On reception of the cleaning execution command, the printer sets the cleaning execution flag to 1 and starts the cleaning operation. When the cleaning operation is completed, the printer immediately resets the cleaning execution flag to 0. In step S305, if a cleaning completion signal indicating that the cleaning execution flag = 0 is received, the no-ink flag corresponding to the color of the cleaned ink cartridge is reset. Then in step S307, the generation of printing information is started again, and the program goes to step S1401 of Figure 16. Alternatively, in the above step S306 of Figure 3, the flag may be reset by the printer itself instead of the host computer.

In step S1401 of Figure 16, if it is concluded that a particular remaining ink flag is 1, that is, the remaining amount of ink in a particular ink cartridge is not enough, then the program goes to step S1407 at which the remaining ink flag is changed to 1. The program then goes to step S1402.

The above-described process of checking the flags in steps S1304 and S1305 of Figure 15 and step S1401 of Figure 16 and the succeeding process according to the result of the checking are performed repeatedly until it is concluded in step S1404 that all image data (printing information) has been output. If it is concluded in step S1404 that all image data (printing information) has been output, the program goes to step S1405 and checks the remaining ink flags.

If all remaining ink flags are 0, that is, there is enough ink in all ink cartridges, then the program goes to step S1302. If an "end" command is not issued in step S1302, then the program returns to step S1303 of Figure 13 and waits for another command telling that generation of printing information should be started.

In step S1405, if it is concluded that a particular remaining ink flag is 1, that is, the remaining amount of ink in a particular ink cartridge is not enough, then the program goes to step S1408 at which the generation of printing information is temporarily stopped. Then in step S1409, a message 3 is displayed. As in the case of Embodiment 1 described above, the message 3 is also displayed in a status window on the display screen as shown in Figure 19. The status window, as shown in Figure 19, contains a message telling that the remaining amount of ink is not enough and thus printing will be stopped before completion if the amount of data to be printed is too large, and also telling the color of that ink. The status window also contains "execute" and "stop" buttons. Either button may be selected via input means such as a mouse or a keyboard of the host computer, so that the selected operation will be executed. After replacing the corresponding ink cartridge with a new one according to the message shown in Figure 19, if the execution button is selected, it is determined in step S1410 of Figure 16 that replacement of the ink cartridge is complete, and the program then goes to step S301 shown in Figure 3. In the case where the stop button is selected in the status window of Figure 19, no ink cartridge is replaced in step S1410 of Figure 16, and it is determined in step S1411 that an "abort" command has been issued, and the program goes to step S1412 to start generation of printing information again. The program then goes to step S1406.

In the case where the program has branched to step S301, a message 4 is displayed. As in the case of Embodiment 1 described above, the message 4 is also displayed in a status window on the display screen as shown in Figure 22. As shown in Figure 22, the status window contains a message telling that the printer will start cleaning the print head, and also contains "execute" and "stop" buttons. Either button may be selected via input means such as a mouse or a keyboard of the host computer, so that the selected operation will be executed. In the case where the stop button is selected, it is determined in step S302 of Figure 3 that a forced aborting command has been issued, and thus the generation of printing information is canceled and the program returns to step S1302 of Figure 15 and waits until a command telling that generation of printing information should be started is issued again. Alternatively, in the case where it has been concluded in the above step S302 of Figure 3 that a forced aborting command has been issued, the program may return to step S1409 of Figure 16 so that the message shown in Figure 19 will be displayed again in the status windows. If the "execute" button is selected in the status window of Figure 22, it is concluded in step S303 of Figure 3 that an "execute" command has been issued, and thus in step S304 a cleaning execution command is sent to the printer. On reception of the cleaning execution command, the printer sets the cleaning execution flag to 1 and starts the cleaning operation. When the cleaning operation is completed, the printer immediately resets the cleaning execution flag to 0. In step S305, if a cleaning completion signal indicating that the cleaning execution flag = 0 is received, the remaining ink flag corresponding to the color of the cleaned ink cartridge is reset. Then in step S307, the generation of printing information is started again, and the program goes to step S1406 of Figure 16. Alternatively, in the above step S306 of Figure 3, the flag may be reset by the printer itself instead of the host computer.

As in the previous embodiments described above, the host computer can know the printer status regarding the presence of ink cartridges, the lack of ink, and the amount of remaining ink. This feature of the present embodiment also provides a great advantage particularly when the printer is installed at a location rather far from the host computer or when the printer is shared by a plurality of computers via a network.

Furthermore, in this embodiment, when the remaining ink in a particular ink cartridge becomes small, the printing operation is stopped after all image data has been printed and then a message is displayed to tell that ink is about to run out. This prevents the printing operation from being unnecessarily stopped during a printing operation.

In Embodiment 1, as described above, the CPU (not shown) of the host computer 110 acquires, via the printer driver 114, the ink status information of the printer 101, such as presence of ink cartridges, lack of ink, and remaining amounts of ink. The host computer displays a proper message (in a status window) on the screen of a display (such as a CRT) depending on the acquired status information. As in the previous embodiments described above, the host computer can know the printer status regarding the presence of ink cartridges, the lack of ink, and the amount of remaining ink. This feature of the embodiment provides a great improvement in the user interface (ease of operation) particularly when the printer 101 is installed at a location rather far from the host computer 110 or when the printer 101 is shared by a plurality of computers via a network.

Furthermore, in Embodiment 2, the data to be printed is analyzed to determine which colors should be used in the printing operation. Ink cartridge flags, no-ink flags, and remaining ink flags are examined only for the determined colors and messages are displayed in a similar manner to Example 1.

For example, when the data to be printed needs only black, only the status information associated with black is checked and the status information associated with other colors is neglected. Thus, it is possible to prevent the reduction in process efficiency (for example efficiency of generation of printing information) due to an unnecessary interrupt to detect the status information. Furthermore, it is possible to prevent a printing operation from being unnecessarily stopped due to the status information regarding a color which is not actually used in the current printing operation.

In Embodiment 3, the status information including the ink cartridge flags, no-ink flags, remaining ink flags is detected depending on the specified color mode (monochrome printing mode, color printing mode), and a proper message is displayed in a similar manner to Embodiment 1. For example, the CPU (not shown) detects only the status information associated with black in the monochrome printing mode, although the status information associated with all colors is detected in the color printing mode. The color mode may be designated by means of selecting operation via the control panel of the printer itself or via a menu displayed on the screen of the host computer. When the color mode is designated via the control panel of the printer, the CPU (not shown) acquires the status information regarding the color mode via the printer driver.

Thus, in this embodiment, it is possible to prevent a processing operation (for example generation of printing information) from being unnecessarily interrupted to detect the status information. For example, when operating in the monochrome printing mode, it is possible to prevent the generation of printing information from being stopped by the status information associated with cyan ink or by a command to replace an ink cartridge which is not actually used.

In Embodiment 4, when operating for example in the monochrome mode, if the remaining amount of ink becomes small, it is possible to continue the printing operation using alternative color ink wherein the alternative color ink is designated via a message displayed on the display screen. For example, when the remaining amount of black ink becomes small, it is possible to continue the printing operation using cyan ink instead of black ink.

This provides an advantage particularly when the printing operation has to be completed without a delay due to the replacement of an ink cartridge.

In Embodiment 5, the number (D) of dots to be printed is determined (in units of pages or band sizes) and compared with the number (Count) of dots that can be printed further. If the comparison result indicates that the number (D) to be printed is smaller than the maximum allowable value (Count), the printing operation is continued further.

In Embodiment 6, the CPU (not shown) can update, via the printer driver, the value representing the number of dots that can be printed further stored in the printer.

In Embodiment 7, the message telling that the amount of ink is about to run out is displayed after the completion of a printing operation.

Now, a color ink jet printer, including a print head, a carriage mechanism, a remaining-ink detector having a reservoir sensor capability, and a paper position detector, which can be used in the present invention, will be described below referring to Figures 25 to 28. The term "paper position" used here refers to the distance between paper (standard paper or thick paper) and a print head.

In an ink-jet printer, it is required that the ink supplying system be capable of supplying ink during a printing operation in such a manner that the amount of supplied ink is exactly equal to the amount emitted from the print head. Furthermore, it is also required that there be no leakage of ink through a nozzle when no printing operation is performed.

For the above purpose, it is known in the art that the ink supplying system has a negative pressure generation mechanism for maintaining the pressure near the nozzle at a level lower than the atmospheric pressure when no printing operation is performed. The term "negative pressure" is used here to denote a pressure that is against the pressure for supplying the ink via the nozzle, that is, the pressure is negative when it is lower than the atmospheric pressure.

Japanese Laid-Open Patent Application No. 63-87242 discloses an ink reservoir having a negative pressure generation mechanism formed in an ink accommodation chamber in the ink reservoir. In the ink-jet print cartridge according to this technique, a foam or sponge material is disposed in almost the entire space in an ink reservoir, and there are provided a plurality of ink emission orifices. In this cartridge, a porous medium such as polyurethane foam is employed as the above-described foam material, and ink is stored in the foam of the medium wherein the capillary force produces a negative pressure which confines the ink in the foam (and thereby prevents the ink from leaking).

Japanese Laid-Open Patent Application No. 6-40043 discloses an ink reservoir including a porous element serving as a negative pressure generation element disposed in an ink accommodation chamber of the ink reservoir, which has a structure for enhancing the ink efficiency and thus increasing the amount of filled ink. In this technique, the ink reservoir has two separate chambers: one is used to accommodate the negative pressure generation element and the other is used to accommodate ink. This structure makes it possible to use almost all ink except for that adhering to the inner wall of the ink accommodation chamber. Thus, this ink reservoir provides high reliability in supplying of ink. Furthermore, this technique offers a high capacity ink reservoir.

In the embodiment described below, the invention is applied to an ink-jet printer using an ink reservoir including a negative pressure generation element made of an absorbing material or a porous material so that the amount of remaining ink is detected by detecting the change in reflectance at the boundary between the ink absorber and the wall of the ink reservoir wherein the detection is performed using a light beam passing through a part of the wall of the ink reservoir thereby achieving high reliability in the detection of the amount of remaining ink.

Figure 28 is a perspective view of a color ink-jet printer having the capability of emitting ink droplets of various colors. Each color ink is stored in its own ink reservoir and mounted on a carriage. The colors of ink include black, cyan, magenta, and yellow, as in common color printers.

In Figure 28, reference numeral 8 denotes a chassis on which various components are mounted. Reference numeral 9 denotes a paper carrying roller which is disposed in the longitudinal direction of the printer in such a manner as to

5 carry paper (not shown). Reference numeral 10 denotes a pinch roller which is disposed in parallel to the paper carrying roller 9 so that the paper is pressed by the pinch roller against the paper carrying roller 9. Reference numeral 2 denotes a guide shaft disposed in parallel to the paper carrying roller 9 at a location opposite to the paper carrying roller 9. Reference numeral 11 denotes a scale of a magnetic linear encoder disposed in parallel to the guide shaft 2 at a location opposite to the guide shaft 2.

10 Reference numeral 1 denotes a carriage adapted to move along the guide shaft 2. Reference numeral 12 denotes a head cover for fixing an ink-jet head (not shown) to the carriage 1. Reference numeral 13 denotes flexible wiring for transmitting a printing data signal from a controller of the printer to an ink-jet head mounted on the carriage 1 and also transmitting an output signal of a sensor (not shown), which is disposed on the carriage 1 so as to sense the magnetic linear encoder, to the controller of the printer.

15 Reference numeral 3 denotes a supporting shaft disposed in parallel to the guide shaft 2, by which the carriage 1 that can rotate about the guide shaft 2 is maintained in a proper position. Reference numeral 14 denotes a carriage motor for moving the carriage 1 along the guide shaft 2. Reference numeral 15 denotes a timing belt for transmitting the driving force of the carriage motor 14 to the carriage 1. Reference numeral 16 denotes a photo interrupter of the transmission type which is disposed at a location in the middle of the path along which the carriage 1 moves so that the home position of the carriage is determined by the photo interrupter 16.

20 Reference numeral 17 denotes a suction cap for preventing the ink-jet head from an ink emission failure and also for recovering the ink emission failure. Reference numeral 18 denotes a protection cap for protecting the ink-jet head so that the inside of the emission nozzle of the ink-jet head is not dried when the ink-jet head is at a waiting position. Reference numeral 5 denotes a paper position selection lever disposed on the carriage 1, for switching the clearance between the printing paper and the ink-jet head depending on the thickness of the printing paper. Reference numeral 6 denotes a photo interrupter of the reflection type serving as an ink sensor disposed at a location near the home position of the carriage 1. Reference numeral 19 denotes a pre-emission hole for receiving ink droplets which are emitted prior to an actual printing operation so as to prevent the nozzle of the ink-jet head from being clogged.

25 Figure 25 is a side view of the carriage 1, and Figure 26 is a side view illustrating the carriage 1 shown in Figure 25 with an ink reservoir mounted on it. Figure 27 is a schematic diagram of the carriage 1 shown in Figure 25, viewed from the direction denoted by the arrow A.

30 Referring to Figures 25, 26, 27, and 28, the positional relationship between the carriage 1 and the photo interrupter 6 and the detection of the carriage 1 by the photo interrupter 6 will be described below.

35 As shown in Figures 25, 26, and 27, holes 1b are formed in a lower part of the carriage 1 so that the light emitted by the photo interrupt 6 may pass through these holes 1b.

40 In Figure 30, reference numeral 21 denotes a print head having a nozzle 22 via which ink droplets are emitted thereby forming an image on paper. Reference numeral 7 denotes an ink reservoir mounted on the carriage 1. Reference numeral 7a denotes an absorber serving as a negative pressure generating element disposed in the ink reservoir. Reference numeral 7b denotes the boundary between the absorber 7a disposed in the ink reservoir and the outer wall of the ink reservoir. Reference 7c denotes an ink accommodation chamber (raw ink accommodation chamber) for accommodating ink (raw ink) without mixing it with other elements. Reference 7d denotes a boundary between the raw ink in the ink reservoir and the outer wall of the ink reservoir. The raw ink accommodation chamber accommodates ink in a substantially closed space. Ink in this ink accommodation chamber is transported into the chamber, in which the ink absorber 7a is disposed, via a gap 7f formed at a lower position of the partition 7g. The ink reservoir 7 is made of a transparent material such as transparent plastic so that the light to be detected by the photo interrupter 6 can pass through the material. Reference numeral 28 denotes a communicating aperture. Ink is supplied to the print head via an ink supply aperture.

45 The ink reservoir 7 also has an atmospheric vent 7h formed in a portion of the partition 7g disposed between the raw ink accommodation chamber and the chamber for accommodating the ink absorber 7a serving as a negative pressure generation element. Furthermore, a negative pressure generation element adjustment space 7i is also formed in a portion of the partition 7g. The atmospheric vent 7h is formed such that it extends from the middle of the partition 7g to the end of the partition 7g, that is, to the gap 7f between the partition and the bottom of the ink cartridge wherein the atmospheric vent 7h is formed at the side adjacent to the chamber for accommodating the negative pressure generation element. The negative pressure generation element adjustment space 7i having a recessed shape is formed between the ink absorber 7a and the partition.

50 As the ink contained in the ink absorber 7a is consumed, the interface between the atmosphere and the liquid ink (gas-to-liquid interface) moves downward and the atmosphere is introduced into the raw ink accommodation chamber, and thus ink is supplied to the ink absorber 7a. This is called gas-to-liquid exchange.

55 The negative pressure in the ink absorber 7a is adjusted by the meniscus position at the gas-to-liquid interface so that ink is supplied without leakage from the print head.

The head 21 and the ink reservoir 7 are mounted as a unit on the carriage 1 and are scanned along the shafts 2 and 3 in a direction perpendicular to the page of the figure.

Figure 29 is a plan view of a board on which the photo interrupter 6 is mounted, wherein reference numeral 6c denotes a light emitting part and reference numeral 6d denotes a light receiving part. In Figure 25, the line 6a denotes an optical path (backward optical path) along which the light 6b, that is emitted by the light emitting part 6c and reflected, travels toward the light receiving part 6d shown in Figure 29. This optical path may lie in the reflection plane parallel to the page of Figure 25 as in the case of the example shown in Figure 25 or may lie in the reflection plane perpendicular to the page of Figure 25. However, if the orientation of the carriage 1 changes to a great degree when the paper position selection lever 5 is operated, it is more preferable that the reflection plane be perpendicular to the page of Figure 25 in that the influence of the change in the orientation becomes smaller. In Figure 25, the optical path is represented by a simple line although the actual light beam is distributed within a certain diameter.

The photo interrupter 6 is disposed such that the detection light strikes a point on the absorber 7a in the ink reservoir 7 wherein the above point is located at a position slightly shifted to the raw ink accommodation chamber 7c. This position of the point influences the number of pages that can be printed further as described in detail later. As for the height at which the photo interrupter 6 is located, it is preferable that the photo interrupter 6 be located so that the focal point of the photo interrupter 6 is near the boundary 7b between the wall of the ink reservoir 7 and the absorber 7a. If the focal point is far from the above boundary 7b, the detection light beam is spread out to a greater extent and thus the detection light beam is reflected by the inner walls of the holes 1b of the carriage 1 or other portions, which results in a reduction in the signal-to-noise ratio in detection.

As described above, the photo interrupter 6 is constructed with an LED or light emitting device 6c serving as a light source and a photo detector 7d wherein the light emitting device 6c and the photo detector 7d are combined into an integral form. The LED emits infrared light that can pass through any of the four color inks described above. The photo detector 6d is adapted to have high enough sensitivity to the wavelength of the above infrared light.

The photo interrupter 6 is disposed separately from the carriage 1 so that the infrared light strikes the bottom face of the absorber 7c via the holes 1b formed in the carriage 1 and further via the transparent wall 7b of the ink reservoir 7 and so that the reflected light reaches the photo detector 6d. An advantage of the above-described construction in which the photo interrupter 6 serving as a detection system is disposed separately from the carriage is that a power supply line and a signal line between the main part of the printer and the photo interrupter 6 are not needed to pass via the carriage that is a movable element, and thus the construction can be simplified.

Figure 31 is an enlarged schematic diagram illustrating a part of the bottom face of the absorber 7a, a point on which is illuminated with the light and also illustrating other portions near that point, in a situation in which there is a sufficient amount of ink in the ink reservoir 7. Figure 31 is an enlarged schematic diagram of the same portions as those shown in Figure 31, in a situation in which no ink remains in the ink reservoir. Figure 33 is a graph illustrating the output of the photo detector 6d of the photo interrupter 6 as a function of the amount of remaining ink.

Now, the principle of detecting the amount of remaining ink will be described below.

In general, the amplitude reflectance of light at an interface between media 1 and 2 having different refractive indices can be represented by Fresnel's equations shown below:

$$rp = (n_2 \cdot \cos\theta_1 - n_1 \cdot \cos\theta_2) / (n_2 \cdot \cos\theta_1 + n_1 \cdot \cos\theta_2) \text{ for p-polarization;}$$

$$rs = (n_1 \cdot \cos\theta_1 - n_2 \cdot \cos\theta_2) / (n_1 \cdot \cos\theta_1 + n_2 \cdot \cos\theta_2) \text{ for s-polarization,}$$

where . . .

n1 is the refractive index of the medium 1;

n2 is the refractive index of the medium 2;

$\theta_1$  is the angle of the light in the medium 1 relative to the normal; and

$\theta_2$  is the angle of the light in the medium 2 relative to the normal.

(There is a relationship  $n_1 \cdot \sin\theta_1 = n_2 \cdot \sin\theta_2$  among these four variables.)

If it is assumed that the light emitted by the light emitting part 6c of the photo interrupter 6 is incident on the ink reservoir 7 at an angle close to a right angle, then  $\cos\theta = 1$  can be considered to be a good approximation. The above equations in terms of the amplitude reflectance can be rewritten in terms of energy reflectance by multiplying them by themselves, and thus the following equation can be obtained:

$$R = (n_1 - n_2)^2 / (n_1 + n_2)^2$$

When there is a sufficient amount of ink in the ink reservoir 7, the gap between the wall of the ink reservoir 7 and the absorber 7a is filled with ink as shown in Figure 31. The ink reservoir 7 and the absorber 7a are both made of plastic having a refractive index of about 1.5 whereas the ink has a refractive index of about 1.4. Therefore, from the above equation, it can be concluded that the reflectance at the wall of the ink reservoir 7 or at the surface of the absorber 7a is as small as about 0.1%.

As the ink is consumed, air is introduced into the gap formed between the absorber 7a and the wall of the ink reservoir 7 via the atmospheric vent 7h shown in Figure 26. Thus, in the situation in which no ink remains in the ink reservoir, the reflectance at the inner wall of the ink reservoir or at the surface of the absorber is about 4%. This means that when all ink has been spent and thus no ink remains, the amount of reflected light has become about 40 times greater than before. (In practice, however, reflection may occur at a position other than the boundary 7c, such as the bottom outer face of the ink reservoir 7. Furthermore, there is noise in a practical system. These factors can reduce the change in the amount of reflected light.)

The detection may also be performed using the light reflected by the boundary 7d between the ink reservoir 7 and the raw ink accommodation chamber 7c. However, there is a difference in the number of possible reflecting locations as shown in Table 1.

TABLE 1

Reflecting Location	Absorber	Raw Ink
Ink Reservoir/Ink	○	○
Absorber/Ink	○	X
Inside of the Absorber	○	X
Total Number	3	1

15  
20

As can be seen from Table 1, the number of reflecting locations that are possible when the detection is performed on the absorber is three times greater than the other case. Therefore, the detection in conjunction with the absorber results in a greater amount of reflected light and thus it is possible to achieve high reliability in detection regardless of noise.

Furthermore, as shown in Figure 32, air introduced into the gap between the absorber 7a and the wall of the ink reservoir 7 exists there in the form of a great number of small bubbles, which scatter the light. This scattering effect results in a further increase in the amount of reflected light.

30 The reflectance described above is obtained assuming that  $\cos\theta = 1$ . Even in the case where the above assumption is not valid, a rather great change in reflectance occurs when the ink is gone. In either case, the output level of the light receiving part 6d of the photo interrupter 6 changes to a great degree corresponding to the change in reflectance and thus it is possible to detect whether there is ink in the ink reservoir 7 on the basis of the change in the output level.

35 In practice, the region illuminated by light is not a point even when the illuminated area is at the focal point of the photo interrupter 6, and has a certain expansion. Therefore, as ink goes out from that region, the output of the photo interrupter 6 changes continuously.

40 In Figure 33, the vertical axis represents the output of the photo interrupter 6, and the horizontal axis represents the number of pages that can be printed further until all ink has been spent. If the output level of the photo interrupter 6 becomes greater than a threshold level defined in the characteristic curve shown in Figure 33 (in the example shown in Figure 33, the threshold level corresponds to an output level which gives 15 as the number of pages that can be printed further), the amount of ink remaining in the ink reservoir is considered as having become very small, and an alarm LED or the like disposed on the control panel of the printer is lighted to tell a user that the ink is about to run out.

45 The number of pages that can be printed further can be changed by changing the threshold level. However, as can be seen from Figure 33, it is unsuitable to select a value lower than the turning point (30 pages in the example shown in Figure 33) at which the output rises up. The turning point itself can be changed by adjusting the detection position of the photo interrupter 6. Thus, it is possible to issue a warning when the number of pages that can be printed further becomes lower than a threshold that can be set to a desired value.

50 Alternatively, the printing operation may be stopped instead of giving a warning, or otherwise at the same time as a warning is given. The stopping of the printing operation may serve as a stronger warning.

55 As described in detail above, the ink reservoir 7 including the absorber 7a serving as the negative pressure generation element is illuminated by the light emitted by the light emitting part 6c, and the reflected light is detected by the light receiving part 6d. If the amount of ink remaining in the ink reservoir becomes lower than the threshold, such a decrease in the amount of ink is detected by the increase in the output level of the light receiving part 6d.

In this structure, the absorber 7a acts as the negative pressure control element for controlling the negative pressure imposed on the ink supplied from the ink reservoir 7 and also acts as the reflection control element for controlling the reflection of the light emitted by the light emitting part 6c thereby controlling the amount of reflected light. Thus, the reduction in the amount of ink in the ink reservoir including the absorber 7a is detected very precisely.

The ink-jet printer shown in Figure 28 is of the type so-called a color ink-jet printer that can emit ink droplets having various colors. For this purpose, four ink reservoirs corresponding to four individual colors are disposed side by side on

the carriage as shown in Figure 36. The amount of ink remaining in each ink reservoir can be detected by moving the carriage 1 so that the ink reservoirs for individual colors come to a position facing the photo interrupter 6 one by one. Since the output should be monitored separately for each color, memory means is provided for each color. It is desirable that the warning of the lack of ink be displayed independently for all four colors. However, the warning may be displayed for only one color to simplify the display panel of the ink-jet printer.

According to the technique described above, it is possible to detect the precise amount of ink remaining in the respective ink reservoirs including an ink absorber of the color ink-jet printer wherein only one detecting system is required to detect four colors.

Whereas in the example described above, the bottom face of the ink reservoir 7 is illuminated by light for the purpose of detection, the detection may also be performed by illuminating the side or upper surface of the ink reservoir 7.

However, it is more preferable that the bottom face of the ink reservoir 7 be employed for the detection for the reason described below.

In general, the density of the absorber 7a is distributed nonuniformly, and thus ink goes spot by spot from the absorber. As a result, the photo interrupter 6 can detect a particular spot having no ink although there is still enough ink in other parts of the absorber, or, in the opposite case, can detect a particular spot having ink although no ink remains in the other parts. This results in a variation in the value that is indicated as the number of pages that can be printed further when the output level reaches the given same threshold. In the worst case, all ink will go before a warning is given.

The ink distribution in the ink reservoir 7 is influenced by gravitation, and ink tends to gather in a bottom region of the ink reservoir 7. This means that ink is distributed more uniformly in the bottom region of the ink reservoir 7. As can be seen from the above discussion, the bottom face is suitable for achieving high accuracy detection of the amount of remaining ink.

In another embodiment shown in Figure 34, two photo interrupters are employed and the average value of the outputs of these two photo interrupters is used to detect the reduction in the amount of remaining ink so as to avoid the influence of the nonuniformity of the density of the absorber 7a and thus achieve high accuracy detection of the amount of remaining ink.

In Figure 34, similar elements to those in Figure 26 are denoted by the same reference numerals as those in Figure 26. Reference numeral 6' denotes a photo interrupter serving as a second ink sensor, which is the same type as the photo interrupter 6. (Hereinafter, the photo interrupter 6 will also be referred to as a first photo interrupter for convenience of explanation.)

In the construction shown in Figure 34, the average of the outputs of the first and second photo interrupters 6 and 6' is used to detect the reduction in the amount of remaining ink. The averaging may be performed either in a simple fashion or in a weighted fashion. The second photo interrupter 6' is disposed at a location nearer to an ink supply aperture 24 compared to the location of the first interrupter 6. As a result, the change in the output of the photo interrupter 6' occurs at a lower value of the number of pages that can be printed further, compared to the case of the first photo interrupter 6. Therefore, either photo interrupter may be weighted more depending on the desired threshold value associated with the number of pages that can be printed further.

If a plurality of sensors for detecting the amount of remaining ink are disposed at different locations so that the average of outputs of these sensors is used for the detection as in the above example, it is possible to reduce the influence of the nonuniformity of the density of the absorber 7a and thus high reliability detection of the amount of remaining ink is possible.

Another technique to reduce the variation in the detected value due to the influence of the nonuniformity of the density of the absorber 7a is to change the location of the photo interrupter 6 relative to the location of the carriage 1 so that the measurement is performed at a plurality of points of the ink reservoir 7 and the average of the measured value at these points is used to detect the amount of remaining ink. In this case, the photo interrupter 6 may be moved, or otherwise the carriage 1 may be moved while maintaining the photo interrupter 6 at a fixed location, so that the measurement is performed at a plurality of points.

In the above-described technique of detecting the amount of remaining ink, when the output of the photo interrupter 6 becomes greater than a predefined threshold, a warning is given and/or the printing operation is stopped. Alternatively, instead of giving a warning or stopping the printing operation when the output of the sensor becomes greater than the threshold voltage, an indication corresponding to the output of the photo interrupter 6 may be displayed in such a manner that, for example, the indication is proportional to the output of the photo interrupter 6 or otherwise in simple relation to the output of the photo interrupter 6.

As shown in Figure 33, the output of the photo interrupter 6 continuously increases with the decreasing amount of ink remaining in the ink reservoir 7 in a small-amount range. Therefore, if an indication corresponding to the output is given, then the indication will represent the number of pages that can be printed further. This indication will give more detailed information about the amount of remaining ink to a user.

Figure 35 illustrates an example of an indication of the amount of ink remaining in the ink reservoir, given on a display panel. In the example of the indication on the display panel shown in Figure 35, the level of a digital meter changes according to the number of pages that can be printed further. Alternatively, the number of pages that can be printed

further may be displayed in a numerical fashion. The display panel may be of any type that is used broadly, such as a liquid crystal display. Furthermore, the indication may be given not only via visual means, but also via audible means. For example, a voice may tell the number of pages that can be printed further. Or otherwise, a buzzer is sounded a number of times depending on the number of pages that can be printed further or a buzzer is sounded for a time period which changes depending on the number of pages that can be printed further.

In this technique, as described above, a user can get detailed information about the amount of remaining ink which is given on the basis of the output of the photo interrupter 6 and thus the user can take proper action such as replacement of an ink reservoir at a right time.

In the example shown in Figure 26, the ink reservoir 7 includes both the absorber 7a and the raw ink storing region 10 7c. Alternatively, the ink reservoir 7 may also be constructed such that an absorber 7a is disposed over the entire region in the ink reservoir 7 as shown in Figure 30.

In the construction shown in Figure 30, the ink in the absorber 7a, flows via the ink supply aperture 24, and a path 30 disposed in the print head 21 and finally reaches the nozzle 22 serving as ink emission means. Thermal energy is applied to the ink by heating means (also referred to as a heater) 31 disposed in the nozzle 22. The abrupt acquiring of 15 thermal energy causes the ink to be ejected via the emission aperture at the end of the nozzle 22. The ink droplets emitted in this way are deposited on a medium such as paper whereby printing is performed.

When there is no ink reservoir 7, the light emitted by the photo interrupter 6 is reflected by nothing. As a result, the 20 output level of the photo interrupter 6 becomes extremely low compared to the level obtained when there is an ink reservoir 7 containing enough amount of ink. This make it possible to detect whether an ink reservoir 7 is mounted or not by judging the output level detected by the photo interrupter 6.

In particular, in a color ink-jet printer such as that shown in Figure 28, it is possible to individually detect the presence 25 or the absence of ink reservoirs for various colors. This prevents the printer from starting a printing operation when an ink reservoir is not mounted on the carriage. Furthermore, in this technique, no additional elements are required to detect whether all ink reservoirs are mounted or not. Thus, it is possible to detect both the amount of remaining ink and the presence or absence of ink reservoirs with a simple construction at a low cost.

In this technique, as described above, there is provided detection means by which the change in reflectance at the 30 boundary between the wall of an ink reservoir and the ink absorber is detected through a part of the wall of the ink reservoir. The amount of remaining ink is detected on the basis of the difference between the reflectance obtained when there is ink at the detection point and that obtained when no ink is present there. This technique offers high reliability 35 detection of the amount of remaining ink, that can detect whether the amount of remaining ink becomes smaller than a predefined threshold even for an ink reservoir including an ink absorber.

Now, a technique for detecting the paper position, that is, the distance between the head and paper using a photo 40 interrupter 6 (sensor) will be described below.

In this technique, the paper position is detected utilizing the fact that the detection level of the photo interrupter 6 (sensor) changes depending on the detection distance.

As described earlier, status information about the presence or absence of an ink reservoir and the carriage position 45 is transmitted to the host computer via the bidirectional interface.

Figure 37 is a cross-sectional front view of a carriage on which a print head and ink reservoirs are mounted. As 50 shown in Figure 37, print head 303 and ink reservoirs 302 are mounted on a carriage 208. The carriage 208 is moved along the shafts 306 and 307 in a direction parallel to the page of Figure 37. There is disposed a photo interrupter 6 (sensor) including an LED and a photo detector constructed in an integral form, at a proper location in the middle of the moving path of the carriage 208 so that the bottom face of an absorber 302a is illuminated by light via holes 212 formed in the carriage 208. The LED emits infrared light that can pass through any of the four color inks including black, cyan, magenta, and yellow inks, which are used broadly in various color printers. The photo detector is adapted to have high 45 enough sensitivity to the wavelength of the light emitted by the LED. A reflection plate 217 is disposed at a fixed position on the carriage 208.

An advantage of the above-described arrangement in which the photo interrupter 6 is disposed separately from the carriage 208 is that it is not required to have a power supply line and a signal line connected to a movable element from the main part of the printer. Since the print head 303 and the ink reservoirs 302 mounted on the carriage 208 are moved 55 as a unit along the shafts 306 and 307 in a direction parallel to the page of the figure, it is possible to detect the presence or absence of ink reservoirs for four colors including black, cyan, magenta, and yellow, as well as the paper position of the carriage using only a single photo detector 6 (sensor) by controlling the position of the carriage 208.

Figure 38 is a cross-sectional view of the carriage 208 wherein the cross section is taken along a plane perpendicular to the shafts. This carriage 208 is supported by the shafts 306 and 307, and the ink reservoirs 302 and the print head 303 are mounted on the carriage. Ink is supplied from the ink reservoirs 302 to the print head 303. The supplied ink is then emitted via an orifice 305 thereby depositing ink on a printing material. The photo interrupter 6 (sensor) is fixed to the main part of the printer. When the paper position is in the standard paper position shown in Figure 38, the photo interrupter 6 (sensor) is about 4.4 mm apart from the bottom of the ink reservoirs. There is also provided a paper position adjustment lever 301. This is used to adjust the carriage position so that the distance between the nozzle disposed at

the end of the head and the paper surface against which ink is fired is maintained constant for both types of paper: standard paper which is broadly used to print a document; and thick paper such as post cards, wherein it is a general requirement for a standard printer to have the capability of printing on both standard and thick paper.

Figure 39 illustrates the carriage 208 in a situation in which the paper position lever 301 has been moved upward to the thick paper position. If the paper position lever is moved in the direction denoted by the arrow, a paper position switching element goes outward and thus the carriage moves upward by means of rotation about the shaft 306. As a result, the distance between the head and the printing paper becomes larger. In this thick paper position, the carriage is located at an angle of about 4 degrees to the paper plane. In this situation, the photo detector 6 is located at a position about 7 mm apart from the ink reservoirs 302. The carriage position shown in Figure 39 is referred to as the thick paper position. The thick paper position is employed when a printing operation is performed on paper thicker than standard paper. Figure 40 illustrates a cap position.

Figure 50 is a graph showing the sensor output of the photo interrupter 6 (sensor) as a function of the distance between the sensor and the reflecting object. The sensor output has a maximum value when the distance between the sensor and the reflecting object is equal to the focal distance. The sensor output becomes lower when the distance between the sensor and the reflecting object is either smaller or greater than the focal distance.

If the sensor-to-reflector distance is smaller than the focal distance in the standard paper position, a problem occurs in detection of the paper position of the above-described carriage 208. That is, when the paper position is switched to the thick paper position the sensor output can either increase or decrease, and therefore it is impossible to determine the paper position. For this reason, the distance between the photo interrupter 6 (sensor) and the reflecting plate 27 is set to a value greater than the focal distance in the standard position. In this case, when the paper position is switched to the thick paper position, the distance between the sensor and the reflecting mirror increases and therefore the sensor output decreases. Thus, it is possible to tell that the paper position is in the thick paper position. If no ink reservoir is mounted on the carriage, the sensor-to-reflector distance becomes infinite (can be regarded as infinite) and therefore the sensor output decreases further to an extremely low level. This means that this technique can also detect whether there is an ink reservoir or not.

Figure 41 illustrates the appearance of a printer, wherein the printer includes a panel switch 601 for a setting operation, a printed paper tray 602, a cover 603 of the main part of the printer, a paper feeding tray 604, an auxiliary paper feeding tray 605, and a paper selection lever 606. When a printing operation is performed using a conventional printer of a similar type, either the standard paper position or the thick paper position is selected by the paper position adjustment lever 301 shown in Figures 38-40, setting regarding the paper position is performed again via the panel switch 601, and the paper selection lever 606 is operated so that either standard or thick paper is selected. Unlike the conventional printer, the printer according to the present embodiment of the invention has the capability of setting the paper position to either the standard paper position or the thick paper position depending on the result of the detection by the photo interrupter 6 (sensor). Furthermore, the status information about the presence or absence of ink reservoirs and the paper position detected by the photo interrupter 6 (sensor) is transmitted to the host computer 110 via the bidirectional interface.

Figure 42 is a flowchart relating to the programmed operation of the printer 101. The program is stored in a program memory such as a ROM (not shown) disposed in the printer 101 so that the program is executed by a controller (CPU) 102.

After turning on the power in step S1501, the program checks, in step S1502, whether all ink reservoirs are mounted since there is a possibility that a user has removed an ink reservoir or operated the paper position adjustment lever. If it is turned out that all ink reservoirs are mounted on the carriage, then the printer is regarded as ready to start a printing operation and thus the program goes to step S1506 at which the program waits for incoming print information. On the other hand, if it is turned out in step S1502 that a particular ink reservoirs are not mounted on the carriage, then the programs goes to step S1503 in which the operation mode is switched to the bidirectional communication mode. In step S1505, if the operation in the bidirection communication mode is complete then the program goes to step S1506 at which the program waits for incoming print information.

Figures 40A-40C comprise a flowchart relating to the programmed operation of the host computer 110. The program for this operation is stored in the device driver 114 of the host computer 110 and the program is executed by a CPU (not shown).

If a user issues a command via a keyboard (not shown) or a pointing device (not shown) to tell the host computer to start a printing operation, then in step S1601 the CPU (not shown) of the host computer 110 sets the operation mode of the host computer to the bidirectional communication mode via the OS system 111 and transmits a command to the printer 101 via the bidirectional interface to tell the printer that the operation mode should be switched to the bidirectional communication mode. On reception of this command, the printer 101 switches its operation mode to the bidirectional communication mode. In step S1602, the CPU (not shown) transmits a detection command to the printer 101 to tell it to detect the carriage position and the presence or absence of individual ink reservoirs. Then in step S1603, the CPU (not shown) receives, from the printer 101, the status information about the carriage position and the presence or absence of the individual ink reservoirs. In step S1604, the CPU (not shown) analyzes the status information received in step S1603 to determine whether all ink reservoirs are mounted on the carriage. If it is concluded in step S1604 that a

particular ink reservoir is not mounted on the carriage, then the CPU (not shown) displays, via the OS system 111, a no-ink dialog in a status window 115 on the display screen as shown in Figure 46. As shown in Figure 46, the no-ink dialog (status window) contains a message telling that a particular ink reservoir is not mounted on the carriage and also telling the color of that reservoir. The no-ink dialog also contains "alternative color" and "stop" buttons via which the user can select the following operation. The user can select either button via the keyboard (not shown) or the pointing device (not shown) of the host computer 110. In step S1619, it is determined whether the "alternative color" button has been selected. If it is turned out that the "alternative color" button is not selected, the "stop" button is considered to be selected, and thus in step S1622 an error dialog 1 is displayed in a status window 115 as shown in Figure 44. As shown in Figure 44, the error dialog contains a message telling that an error occurs in the printing operation and also telling that an ink reservoir for a corresponding color ink should be mounted. The error dialog also contains "stop printing" and "OK" buttons via which the user can designate the following operation. The user can select either button via the keyboard (not shown) or the pointing device (not shown) of the host computer 110. In step S1623, it is determined whether the "stop printing" button has been selected. If it is turned out that the "stop printing" button has been selected, then the program goes to step S1624 in which the bidirectional communication mode is terminated. Then at step S1625, the entire process is completed.

In the above-described step S1623, if it is concluded that the "stop printing" button is not selected, the "OK" button is considered to be selected, and thus the program returns to step S1604 to determine whether an ink reservoir for the designated color ink has been mounted.

On the other hand, in the above-described step S1619 if it is concluded that the "alternative color" button has been selected, then the CPU (not shown) displays, via the OS system 111, an alternative color dialog in a status window 115 as shown in Figure 47. As shown in Figure 47, the alternative color dialog (status window) contains a message asking the user whether he/she wants to perform the printing operation using for example a process black color obtained by mixing yellow, magenta, and cyan when for example a black ink reservoir is not mounted on the carriage. The alternative color dialog also contains "cancel" and "OK" buttons by which the user can select the following operation. Whereas the alternative color can be designated by the user in the example described above, the program may automatically designate the alternative color and may display the designated color. The user can select either button via the keyboard (not shown) or the pointing device (not shown) of the host computer 110. If the alternative color is designated, then the program goes to step S1621 in which the no-ink-reservoir flag is set to 1 (ink reservoir flag = 1). Then the program goes to step S1606.

In the above-described step S1604, if it is concluded that all ink reservoirs are mounted on the carriage, then the CPU (not shown) resets the no-ink-reservoir flag to 0 (ink reservoir flag = 0) in step S1605. Then in step S1606, the CPU analyzes the status information received from the printer 101 to determine whether the carriage position is at the standard paper position. If it is turned out that the carriage position is not at the standard paper position, then the carriage position is considered to be at the thick paper position and the program goes to step S1607 to display a thick paper print dialog in a status window 115 as shown in Figure 47. The thick paper print dialog (status window) contains a virtual image of the printer 101 to indicate the location of the paper selection lever disposed on the right side of the automatic sheet feeder and also contains a message telling the user to check whether the paper selection lever is in the thick paper position. The thick paper print dialog (status window) also contains "cancel" and "print" buttons by which the user can designate the following operation. The user can select either button via the keyboard (not shown) or the pointing device (not shown) of the host computer 110. After the range of pages to be printed (all pages or a particular range) and the number of sets to be printed are designated, if the "print" button is selected, then the program goes to step S1610 at which the bidirectional communication mode is terminated. The program then executes the steps following the step S1610.

In the above-described step S1606, if it is concluded that the carriage position is in the standard paper position, then the program goes to step S1609 to display a standard paper print dialog in a status window 115 as shown in Figure 48. The thick paper print dialog (status window) shown in Figure 48 contains a virtual image of the printer 101 to indicate the location of the paper selection lever disposed on the right side of the automatic sheet feeder and also contains a message telling the user to check whether the paper selection lever is in the standard paper position. The standard paper print dialog (status window) shown in Figure 48 also contains "cancel" and "print" buttons by which the user can designate the following operation. The user can select either button via the keyboard (not shown) or the pointing device (not shown) of the host computer 110. After the range of pages to be printed (all pages or a particular range) and the number of sets to be printed are designated, if the "print" button is selected, then the program goes to step S1610 at which the bidirectional communication mode is terminated.

In step S1611, it is determined whether the user has selected the "print" button via the keyboard (not shown) or the pointing device (not shown) of the host computer 110. If it is turned out that the "print" button is not selected, then the program goes to step S1612 at which the entire process is completed. On the other hand, if it is concluded in step S1611 that the "print" button has been selected, then the program goes to step S1613 to transmit printing data (printing information) to the printer 101. In step S1614, if the transmission of the printing data (printing information) is completed, then in step S1615 it is determined whether the no-ink-reservoir flag is 0. If the no-ink-reservoir flag is 0, then the entire process is completed. On the other hand, if the no-ink-reservoir flag is 1, that is, the printing operation is in the alternative

color printing mode, then the program goes to step S1616 to display an error dialog 2 in a status window 115 as shown in Figure 45. The error dialog 2 shown in Figure 45 contains a message telling that the printing operation has been performed using for example process black designated by the user instead of, for example, black and also contains a message telling the user to mount a black ink reservoir. The error dialog 2 also contains an "OK" button. The user can 5 select this button via the keyboard (not shown) or the pointing device (not shown) of the host computer 110. If the user selects the "OK" button, then the program goes to step S1617 at which the whole process is completed.

In an alternative embodiment, a sensor such as a microswitch (not shown) 607 is linked to the paper selection lever 606 shown in Figure 41 so that the position of the paper selection lever is detected by the sensor 607 and the detected 10 position of the paper selection lever is transmitted as the status information to the host computer 110. The received status information may be displayed in a status window 115 as in the above-described embodiment.

As described above, the printer system according to the present embodiment of the invention has the capability of detecting the presence or absence of ink reservoirs in the ink-jet printer as well as the carriage position, wherein the detected information is shown to the user via the host computer. Thus, the user can get useful information and can select 15 a proper operation from various options.

15 The individual components shown in outline or designated by blocks in the drawings are all well-known in the image processing and recording arts and their specific construction and operation are not critical to the operation or best mode for carrying out the invention.

While the present invention has been described with respect to what is currently considered to be the preferred 20 embodiments, it is to be understood that the invention is not limited to the disclosed embodiments. To the contrary, the invention is intended to cover various modifications and equivalent arrangements included within the spirit and scope of the appended claims. The scope of the following claims is to accorded the broadest interpretation so as to encompass 25 all such modifications and equivalent structures and functions.

A host computer acquires information about an amount of remaining ink of a printer. In response to the acquired 25 information about the amount of remaining ink, the host computer displays a message on a display screen so that a user can select whether an ink cartridge is to be replaced with a new one or the process is to return to a previous routine without replacing the ink cartridge.

## Claims

- 30 1. An information processing system for controlling a printing apparatus, said system comprising:  
acquisition means for acquiring remaining-amount information representing the amount of ink remaining in an ink cartridge disposed in the printing apparatus; and  
display control means for controlling display of a message on display means in response to the acquired remaining-amount information, the message advising a user to select either replacing of the ink cartridge in the printing apparatus or returning to a process performed by said information processing system.
2. An information processing system according to Claim 1, further comprising means for generating printing information to be printed by the printing apparatus and means for outputting the printing information to the printing apparatus.
- 40 3. An information processing system according to Claim 2, wherein the printing information comprises image information.
4. An information processing system according to Claim 2, wherein said outputting means outputs the printing information to the printing apparatus via a bidirectional interface.
- 45 5. An information processing system according to Claim 2, wherein said display control means controls display of the message on the display means after outputting the printing information to the printing apparatus.
6. An information processing system according to Claim 1, wherein the process performed by said information processing system comprises generation of printing information to be printed by the printing apparatus.
- 50 7. An information processing system according to Claim 1, wherein said acquisition means acquires the remaining-amount information from the printing apparatus via a bidirectional interface.
8. An information processing system according to Claim 1, further comprising the printing apparatus, wherein said printing apparatus is of an ink-jet type that performs a printing operation by emitting ink.
- 55 9. An information processing system according to Claim 8, wherein said ink cartridge of said printing apparatus includes: a first accommodation chamber for accommodating a negative pressure generation element, said first

accommodation chamber including an atmospheric vent for communicating with the atmosphere; and a second accommodation chamber for directly accommodating ink to be supplied to said first accommodation chamber, said second accommodation chamber communicating with said first accommodation chamber only via a small duct disposed at a location apart from said atmospheric vent.

5           10. An information processing system according to Claim 9, wherein the remaining-amount information represents the amount of ink remaining in said second accommodation chamber of said ink cartridge.

10           11. An information processing system for controlling a printing apparatus, said system comprising:  
                  analysis means for analyzing a color to be used by the printing apparatus;  
                  acquisition means for acquiring remaining-amount information from the printing apparatus, the remaining-amount information representing the amount of ink remaining in an ink cartridge, the ink having the color analyzed by said analysis means; and  
                  display control means for controlling display of a message on display means in response to the acquired remaining-amount information, the message advising a user to select either replacing of the ink cartridge containing ink having the color to be used by the printing apparatus or returning to a process performed by said information processing system.

15           12. An information processing system according to Claim 11, further comprising means for generating printing information to be printed by the printing apparatus and means for outputting the printing information to the printing apparatus.

20           13. An information processing system according to Claim 12, wherein the printing information comprises image information.

25           14. An information processing system according to Claim 12, wherein said outputting means outputs the printing information to the printing apparatus via a bidirectional interface.

30           15. An information processing system according to Claim 12, wherein said display control means controls display of the message on the display means after outputting the printing information to the printing apparatus.

35           16. An information processing system according to Claim 11, wherein the process performed by said information processing system comprises generation of printing information to be printed by the printing apparatus.

40           17. An information processing system according to Claim 11, wherein said acquisition means acquires the remaining-amount information from the printing apparatus via a bidirectional interface.

45           18. An information processing system according to Claim 11, further comprising the printing apparatus, wherein said printing apparatus is of an ink-jet type that performs a printing operation by emitting ink.

50           19. An information processing system according to Claim 18, wherein said ink cartridge of said printing apparatus includes: a first accommodation chamber for accommodating a negative pressure generation element, said first accommodation chamber including an atmospheric vent for communicating with the atmosphere; and a second accommodation chamber for directly accommodating ink to be supplied to said first accommodation chamber, said second accommodation chamber communicating with said first accommodation chamber only via a small duct disposed at a location apart from said atmospheric vent.

55           20. An information processing system according to Claim 19, wherein the remaining-amount information represents the amount of ink remaining in said second accommodation chamber of said ink cartridge.

50           21. An information processing system for controlling a printing apparatus, said system comprising:  
                  judgement means for judging whether a printing mode of the printing apparatus is a monochrome mode or a color mode;  
                  acquisition means for acquiring remaining-amount information from the printing apparatus in response to a judgement result by said judgement means, the remaining-amount information representing the amount of ink of a color to be used remaining in an ink cartridge; and  
                  display control means for controlling display of a message on display means in response to the acquired remaining-amount information, the message advising a user to select either replacing of the ink cartridge containing ink having the color to be used by the printing apparatus or returning to a process performed by said information processing system.

22. An information processing system according to Claim 21, wherein in a case where said judgement means concludes that the printing mode is the monochrome mode, said acquisition means acquires the remaining-amount information representing the amount of ink remaining in a black color ink cartridge.

5 23. An information processing system according to Claim 21, wherein in a case where said judgement means concludes that the printing mode is the color mode, said acquisition means acquires the remaining-amount information representing the amounts of ink remaining in ink cartridges containing color inks to be used in the color mode.

10 24. An information processing system according to Claim 21, further comprising means for generating printing information to be printed by the printing apparatus and means for outputting the printing information to the printing apparatus.

25. An information processing system according to Claim 24, wherein the printing information comprises image information.

15 26. An information processing system according to Claim 24, wherein said outputting means outputs the printing information to the printing apparatus via a bidirectional interface.

20 27. An information processing system according to Claim 24, wherein said display control means controls display of the message on the display means after outputting the printing information to the printing apparatus.

28. An information processing system according to Claim 21, wherein the process performed by said information processing system comprises generation of printing information to be printed by the printing apparatus.

25 29. An information processing system according to Claim 21, wherein said acquisition means acquires the remaining-amount information from the printing apparatus via a bidirectional interface.

30 30. An information processing system according to Claim 21, further comprising the printing apparatus, wherein said printing apparatus is of an ink-jet type that performs a printing operation by emitting ink.

35 31. An information processing system according to Claim 30, wherein said ink cartridge of said printing apparatus includes: a first accommodation chamber for accommodating a negative pressure generation element, said first accommodation chamber including an atmospheric vent for communicating with the atmosphere; and a second accommodation chamber for directly accommodating ink to be supplied to said first accommodation chamber, said second accommodation chamber communicating with said first accommodation chamber only via a small duct disposed at a location apart from said atmospheric vent.

32. An information processing system according to Claim 31, wherein the remaining-amount information represents the amount of ink remaining in said second accommodation chamber of said ink cartridge.

40 33. An information processing system for controlling a printing apparatus, said system comprising:  
acquisition means for acquiring remaining-amount information representing the amount of ink remaining in an ink cartridge disposed in the printing apparatus; and  
display control means for controlling display of a message on display means in response to the acquired remaining-amount information, the message advising a user to select either replacing of the ink cartridge in the printing apparatus or designation of an alternative color different from color of the ink in the ink cartridge.

45 34. An information processing system according to Claim 33, further comprising means for generating printing information to be printed by the printing apparatus and means for outputting the printing information to the printing apparatus.

50 35. An information processing system according to Claim 34, wherein the printing information comprises image information.

36. An information processing system according to Claim 34, wherein said outputting means outputs the printing information to said printing apparatus via a bidirectional interface.

55 37. An information processing system according to Claim 34, wherein said display control means controls display of the message on the display means after outputting the printing information to the printing apparatus.

38. An information processing system according to Claim 33, wherein said acquisition means acquires the remaining-amount information from the printing apparatus via a bidirectional interface.

5 39. An information processing system according to Claim 33, further comprising the printing apparatus, wherein said printing apparatus is of an ink-jet type that performs a printing operation by emitting ink.

10 40. An information processing system according to Claim 39, wherein said ink cartridge of said printing apparatus includes: a first accommodation chamber for accommodating a negative pressure generation element, said first accommodation chamber including an atmospheric vent for communicating with the atmosphere; and a second accommodation chamber for directly accommodating ink to be supplied to said first accommodation chamber, said second accommodation chamber communicating with said first accommodation chamber only via a small duct disposed at a location apart from said atmospheric vent.

15 41. An information processing system according to Claim 40, wherein the remaining-amount information represents the amount of ink remaining in said second accommodation chamber of said ink cartridge.

20 42. An information processing system for controlling a printing apparatus, said system comprising:  
acquisition means for acquiring remaining-amount information representing the amount of ink remaining in an ink cartridge disposed in the printing apparatus; and  
display control means for controlling display of a message on display means in response to the acquired remaining-amount information, the message advising a user to select either designation of an alternative color different from a color of the ink in ink cartridge or returning to a process performed by said information processing system.

25 43. An information processing system according to Claim 42, further comprising means for generating printing information to be printed by the printing apparatus and means for outputting the printing information to the printing apparatus.

30 44. An information processing system according to Claim 43, wherein the printing information comprises image information.

35 45. An information processing system according to Claim 43, wherein said outputting means outputs the printing information to said printing apparatus via a bidirectional interface.

40 46. An information processing system according to Claim 43, wherein said display control means controls display of the message on the display means after outputting the printing information to the printing apparatus.

45 47. An information processing system according to Claim 42, wherein the process performed by said information processing system comprises generation of printing information to be printed by said printing apparatus.

50 48. An information processing system according to Claim 42, wherein said acquisition means acquires the remaining-amount information from the printing apparatus via a bidirectional interface.

49. An information processing system according to Claim 42, further comprising the printing apparatus, wherein said printing apparatus is of an ink-jet type that performs a printing operation by emitting ink.

55 50. An information processing system according to Claim 49, wherein said ink cartridge of said printing apparatus includes: a first accommodation chamber for accommodating a negative pressure generation element, said first accommodation chamber including an atmospheric vent for communicating with the atmosphere; and a second accommodation chamber for directly accommodating ink to be supplied to said first accommodation chamber, said second accommodation chamber communicating with said first accommodation chamber only via a small duct disposed at a location apart from said atmospheric vent.

51. An information processing system according to Claim 50, wherein remaining-amount information represents the amount of ink remaining in said second accommodation chamber of said ink cartridge.

52. An information processing system for outputting dot image information to a printing apparatus, said system comprising:  
comparison means for comparing a number of dots contained in the dot image information with a number of dots that can be printed by the printing apparatus; and

control means for controlling the generation of the dot image information depending on a result of said comparison means.

5 53. An information processing system according to Claim 52, wherein if said comparison means determines that the  
number of dots contained in the dot image information cannot be printed by the printing apparatus, said control  
means stops the generation of the dot image information and controls display of a message on display means, the  
message inquiring of a user whether an ink cartridge of the printing apparatus should be replaced.

10 54. An information processing system according to Claim 52, wherein said control means updates the number of dots  
that can be printed, after outputting generated dot image information to the printing apparatus.

15 55. An information processing system according to Claim 52, further comprising acquisition means for acquiring remain-  
ing-amount information from the printing apparatus via a bidirectional interface, the remaining amount information  
representing the amount of ink remaining ink in the printing apparatus, the number of dots that can be printed by  
the printing apparatus corresponding to the remaining-amount information.

20 56. An information processing system according to Claim 52, further comprising means for outputting the dot image  
information to the printing apparatus via a bidirectional interface.

25 57. An information processing system according to Claim 52, further comprising the printing apparatus, wherein said  
printing apparatus is of an ink-jet type that performs a printing operation by emitting ink.

30 58. An information processing method for use in an information processing system for controlling a printing apparatus,  
said method comprising the steps of:  
acquiring remaining-amount information representing the amount of ink remaining in an ink cartridge dis-  
posed in the printing apparatus; and  
controlling display of a message on display means in response to the acquired remaining-amount information,  
the message advising a user to select either replacing of the ink cartridge in the printing apparatus or returning to  
a process performed by the information processing system.

35 59. An information processing method for use in an information processing system for controlling a printing apparatus,  
said method comprising the steps of:  
analyzing a color to be used by the printing apparatus;  
acquiring remaining-amount information from the printing apparatus, the remaining-amount information rep-  
resenting the amount of ink remaining in an ink cartridge, the ink having the color analyzed in said analyzing step; and  
controlling display of a message on display means in response to the acquired remaining-amount information,  
the message advising a user to select either replacing of the ink cartridge containing ink having the color to be used  
by the printing apparatus or returning to a process performed by the information processing system.

40 60. An information processing method for use in an information processing system for controlling a printing apparatus,  
said method comprising the steps of:  
judging whether a printing mode of the printing apparatus is a monochrome mode or a color mode;  
acquiring remaining-amount information from the printing apparatus in response to a judgement result  
obtained in said judging step, the remaining-amount information representing the amount of ink of a color to be used  
remaining in an ink cartridge; and  
controlling display of a message on display means in response to the acquired remaining-amount information,  
the message advising a user to select either replacing of the ink cartridge containing ink having the color to be used  
by the printing apparatus or returning to a process performed by the information processing system.

45 61. An information processing method for use in an information processing system for controlling a printing apparatus,  
said method comprising the steps of:  
acquiring remaining-amount information representing the amount of ink remaining in an ink cartridge dis-  
posed in the printing apparatus; and  
controlling display of a message on display means in response to the acquired remaining-amount information,  
the message advising a user to select either replacing of the ink cartridge in the printing apparatus or designation  
of an alternative color different from a color of the ink in the ink cartridge.

50 62. An information processing method for use in an information processing system for controlling a printing apparatus,  
said method comprising the steps of:

acquiring remaining-amount information representing the amount of ink remaining in an ink cartridge disposed in the printing apparatus; and

5 controlling display of a message on display means in response to the acquired remaining-amount information, the message advising a user to select either designation of an alternative color different from a color of the ink in the ink cartridge or returning to a process performed by the information processing system.

63. An information processing method for use in an information processing system for outputting dot image information to a printing apparatus, said method comprising the steps of:

10 comparing a number of dots contained in the dot image information with a number of dots that can be printed by the printing apparatus; and

controlling the generation of the dot image information depending on a result in said comparing step.

64. An information processing system for controlling a printing apparatus, said system comprising:

15 acquisition means for acquiring information representing the distance between a print head of the printing apparatus and a printing medium; and

display control means for controlling display of identification information about the printing medium in response to the acquired information, the identification information being set in the printing apparatus.

65. An information processing system according to Claim 64, wherein the information representing the distance between 20 the print head of the printing apparatus and the printing medium is detected by detection means disposed in the printing apparatus.

66. An information processing system according to Claim 65, wherein said detection means comprises a sensor.

25 67. An information processing system according to Claim 64, wherein said acquisition means acquires the information from the printing apparatus via a bidirectional interface.

68. An information processing system according to Claim 64, further comprising the printing apparatus, wherein said 30 printing apparatus is of an ink-jet type that performs a printing operation by emitting ink.

69. An information processing system according to Claim 64, wherein the printing medium comprises standard paper.

70. An information processing system according to Claim 64, wherein the printing medium comprises thick paper.

35 71. An information processing system for controlling a printing apparatus, said system comprising:

acquisition means for acquiring information representing an ink cartridge mounting status of the printing apparatus; and

40 display control means for controlling display of a message on display means in response to the acquired information, the message advising a user to select an alternative color different from a color of the ink in said ink cartridge.

72. An information processing system according to Claim 71, wherein the information representing the ink cartridge mounting status is detected, by detection means disposed in the printing apparatus.

45 73. An information processing system according to Claim 72, wherein said detection means comprises a sensor.

74. An information processing system according to Claim 71, wherein said acquisition means acquires the information from the printing apparatus via a bidirectional interface.

50 75. An information processing system according to Claim 71, further comprising the printing apparatus, wherein said printing apparatus is of an ink-jet type that performs a printing operation by emitting ink.

76. An information processing system according to Claim 75, wherein said ink cartridge of said printing apparatus 55 includes: a first accommodation chamber for accommodating a negative pressure generation element, said first accommodation chamber including an atmospheric vent for communicating with the atmosphere; and a second accommodation chamber for directly accommodating ink to be supplied to said first accommodation chamber, said second accommodation chamber communicating with said first accommodation chamber only via a small duct disposed at a location apart from said atmospheric vent.

77. An information processing method for use in an information processing system for controlling a printing apparatus, said method comprising the steps of:  
5           acquiring information representing the distance between a print head of the printing apparatus and a printing medium; and  
          controlling display of identification information about the printing medium in response to the acquired information, the identification information being set in printing apparatus.

78. An information processing method according to Claim 77, wherein the information representing the distance between the print head and the printing medium is detected by detection means disposed in the printing apparatus.

10           79. An information processing method according to Claim 78, wherein the detection means comprises a sensor.

80. An information processing method according to Claim 77, wherein in said acquisition step the information is acquired from the printing apparatus via a bidirectional interface.

15           81. An information processing method according to Claim 77, wherein the printing apparatus is of an ink-jet type that performs a printing operation by emitting ink.

20           82. An information processing method according to Claim 77, wherein the printing medium comprises standard paper.

83. An information processing method according to Claim 77, wherein the printing medium comprises thick paper.

25           84. An information processing method for use in an information processing system for controlling a printing apparatus, said method comprising the steps of:  
          acquiring information representing an ink cartridge mounting status of the printing apparatus; and  
          controlling display of a message on display means in response to the acquired information, the message advising a user to select an alternative color different from a color of the ink in said ink cartridge.

30           85. An information processing method according to Claim 84, wherein the information representing the ink cartridge mounting status is detected by detection means disposed in the printing apparatus.

86. An information processing method according to Claim 85, wherein the detection means comprises a sensor.

35           87. An information processing method according to Claim 84, wherein in said acquisition step the information is acquired from the printing apparatus via a bidirectional interface.

88. An information processing method according to Claim 84, wherein the printing apparatus is of an ink-jet type that performs a printing operation by emitting ink.

40           89. An information processing method according to Claim 84, wherein the ink cartridge of the printing apparatus includes: a first accommodation chamber for accommodating a negative pressure generation element, the first accommodation chamber including an atmospheric vent for communicating with the atmosphere; and a second accommodation chamber for directly accommodating ink to be supplied to the first accommodation chamber, the second accommodation chamber communicating with the first accommodation chamber only via a small duct disposed at a location apart from the atmospheric vent.
